

Chapter 2

Simple Comparative Experiments

Solutions

2-1 The breaking strength of a fiber is required to be at least 150 psi. Past experience has indicated that the standard deviation of breaking strength is $\sigma = 3$ psi. A random sample of four specimens is tested. The results are $y_1=145$, $y_2=153$, $y_3=150$ and $y_4=147$.

- (a) State the hypotheses that you think should be tested in this experiment.

$$H_0: \mu = 150 \quad H_1: \mu > 150$$

- (b) Test these hypotheses using $\alpha = 0.05$. What are your conclusions?

$$n = 4, \quad \sigma = 3, \quad \bar{y} = 1/4 (145 + 153 + 150 + 147) = 148.75$$

$$z_o = \frac{\bar{y} - \mu_o}{\frac{\sigma}{\sqrt{n}}} = \frac{148.75 - 150}{\frac{3}{\sqrt{4}}} = \frac{-1.25}{\frac{3}{2}} = -0.8333$$

Since $z_{0.05} = 1.645$, do not reject.

- (c) Find the P -value for the test in part (b).

$$\text{From the } z\text{-table: } P \cong 1 - [0.7967 + (2/3)(0.7995 - 0.7967)] = 0.2014$$

- (d) Construct a 95 percent confidence interval on the mean breaking strength.

The 95% confidence interval is

$$\begin{aligned} \bar{y} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} &\leq \mu \leq \bar{y} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \\ 148.75 - (1.96)(3/2) &\leq \mu \leq 148.75 + (1.96)(3/2) \end{aligned}$$

$$145.81 \leq \mu \leq 151.69$$

2-2 The viscosity of a liquid detergent is supposed to average 800 centistokes at 25°C. A random sample of 16 batches of detergent is collected, and the average viscosity is 812. Suppose we know that the standard deviation of viscosity is $\sigma = 25$ centistokes.

- (a) State the hypotheses that should be tested.

$$H_0: \mu = 800 \quad H_1: \mu \neq 800$$

- (b) Test these hypotheses using $\alpha = 0.05$. What are your conclusions?

$$z_o = \frac{\bar{y} - \mu_o}{\frac{\sigma}{\sqrt{n}}} = \frac{812 - 800}{\frac{25}{\sqrt{16}}} = \frac{12}{\frac{25}{4}} = 1.92 \quad \text{Since } z_{\alpha/2} = z_{0.025} = 1.96, \text{ do not reject.}$$

(c) What is the P -value for the test? $P = 2(0.0274) = 0.0549$

(d) Find a 95 percent confidence interval on the mean.

The 95% confidence interval is

$$\begin{aligned} \bar{y} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} &\leq \mu \leq \bar{y} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \\ 812 - (1.96)(25/4) &\leq \mu \leq 812 + (1.96)(25/4) \\ 812 - 12.25 &\leq \mu \leq 812 + 12.25 \\ 799.75 &\leq \mu \leq 824.25 \end{aligned}$$

2-3 The diameters of steel shafts produced by a certain manufacturing process should have a mean diameter of 0.255 inches. The diameter is known to have a standard deviation of $\sigma = 0.0001$ inch. A random sample of 10 shafts has an average diameter of 0.2545 inches.

(a) Set up the appropriate hypotheses on the mean μ .

$$H_0: \mu = 0.255 \quad H_1: \mu \neq 0.255$$

(b) Test these hypotheses using $\alpha = 0.05$. What are your conclusions?

$$n = 10, \sigma = 0.0001, \bar{y} = 0.2545$$

$$z_o = \frac{\bar{y} - \mu_o}{\frac{\sigma}{\sqrt{n}}} = \frac{0.2545 - 0.255}{\frac{0.0001}{\sqrt{10}}} = -15.81$$

Since $z_{0.025} = 1.96$, reject H_0 .

(c) Find the P -value for this test. $P = 2.6547 \times 10^{-56}$

(d) Construct a 95 percent confidence interval on the mean shaft diameter.

The 95% confidence interval is

$$\begin{aligned} \bar{y} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} &\leq \mu \leq \bar{y} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \\ 0.2545 - (1.96) \left(\frac{0.0001}{\sqrt{10}} \right) &\leq \mu \leq 0.2545 + (1.96) \left(\frac{0.0001}{\sqrt{10}} \right) \end{aligned}$$

$$0.254438 \leq \mu \leq 0.254562$$

2-4 A normally distributed random variable has an unknown mean μ and a known variance $\sigma^2 = 9$. Find the sample size required to construct a 95 percent confidence interval on the mean, that has total length of 1.0.

Since $y \sim N(\mu, 9)$, a 95% two-sided confidence interval on μ is

$$\bar{y} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \leq \mu \leq \bar{y} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

$$\bar{y} - (1.96) \frac{3}{\sqrt{n}} \leq \mu \leq \bar{y} + (1.96) \frac{3}{\sqrt{n}}$$

If the total interval is to have width 1.0, then the half-interval is 0.5. Since $z_{\alpha/2} = z_{0.025} = 1.96$,

$$(1.96)(3/\sqrt{n}) = 0.5$$

$$\sqrt{n} = (1.96)(3/0.5) = 11.76$$

$$n = (11.76)^2 = 138.30 \approx 139$$

2-5 The shelf life of a carbonated beverage is of interest. Ten bottles are randomly selected and tested, and the following results are obtained:

Days	
108	138
124	163
124	159
106	134
115	139

- (a) We would like to demonstrate that the mean shelf life exceeds 120 days. Set up appropriate hypotheses for investigating this claim.

$$H_0: \mu = 120 \quad H_1: \mu > 120$$

- (b) Test these hypotheses using $\alpha = 0.01$. What are your conclusions?

$$\bar{y} = 131$$

$$S^2 = 3438 / 9 = 382$$

$$S = \sqrt{382} = 19.54$$

$$t_o = \frac{\bar{y} - \mu_o}{S/\sqrt{n}} = \frac{131 - 120}{19.54/\sqrt{10}} = 1.78$$

since $t_{0.01,9} = 2.821$; do not reject H_0

Minitab Output

T-Test of the Mean

Test of mu = 120.00 vs mu > 120.00

Variable	N	Mean	StDev	SE Mean	T	P
Shelf Life	10	131.00	19.54	6.18	1.78	0.054

T Confidence Intervals

Variable	N	Mean	StDev	SE Mean	99.0 % CI
Shelf Life	10	131.00	19.54	6.18	(110.91, 151.09)

(c) Find the P -value for the test in part (b). $P=0.054$

(d) Construct a 99 percent confidence interval on the mean shelf life.

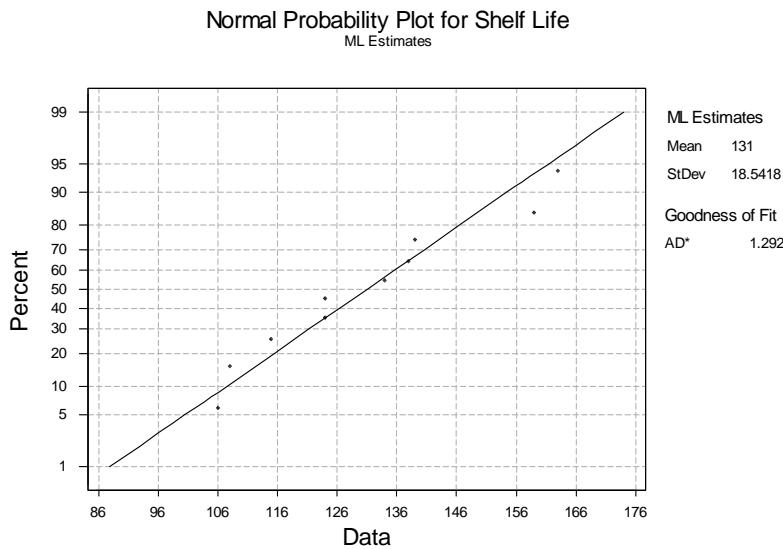

The 99% confidence interval is $\bar{y} - t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} \leq \mu \leq \bar{y} + t_{\alpha/2, n-1} \frac{S}{\sqrt{n}}$ with $\alpha = 0.01$.

$$131 - (3.250) \left(\frac{1954}{\sqrt{10}} \right) \leq \mu \leq 131 + (3.250) \left(\frac{1954}{\sqrt{10}} \right)$$

$$110.91 \leq \mu \leq 151.09$$

2-6 Consider the shelf life data in Problem 2-5. Can shelf life be described or modeled adequately by a normal distribution? What effect would violation of this assumption have on the test procedure you used in solving Problem 2-5?

A normal probability plot, obtained from Minitab, is shown. There is no reason to doubt the adequacy of the normality assumption. If shelf life is not normally distributed, then the impact of this on the t -test in problem 2-5 is not too serious unless the departure from normality is severe.

✓ 2-7 The time to repair an electronic instrument is a normally distributed random variable measured in hours. The repair time for 16 such instruments chosen at random are as follows:

Hours			
159	280	101	212
224	379	179	264
222	362	168	250
149	260	485	170

(a) You wish to know if the mean repair time exceeds 225 hours. Set up appropriate hypotheses for investigating this issue.

$$H_0: \mu = 225 \quad H_1: \mu > 225$$

(b) Test the hypotheses you formulated in part (a). What are your conclusions? Use $\alpha = 0.05$.

$$\bar{y} = 247.50$$

$$S^2 = 146202 / (16 - 1) = 9746.80$$

$$S = \sqrt{9746.8} = 98.73$$

$$t_o = \frac{\bar{y} - \mu_o}{\frac{S}{\sqrt{n}}} = \frac{241.50 - 225}{\frac{98.73}{\sqrt{16}}} = 0.67$$

since $t_{0.05,15} = 1.753$; do not reject H_0

Minitab Output

T-Test of the Mean						
Test of mu = 225.0 vs mu > 225.0						
Variable	N	Mean	StDev	SE Mean	T	P
Hours	16	241.5	98.7	24.7	0.67	0.26
T Confidence Intervals						
Variable	N	Mean	StDev	SE Mean	95.0 % CI	
Hours	16	241.5	98.7	24.7	(188.9, 294.1)	

(c) Find the P-value for this test. $P=0.26$

(d) Construct a 95 percent confidence interval on mean repair time.

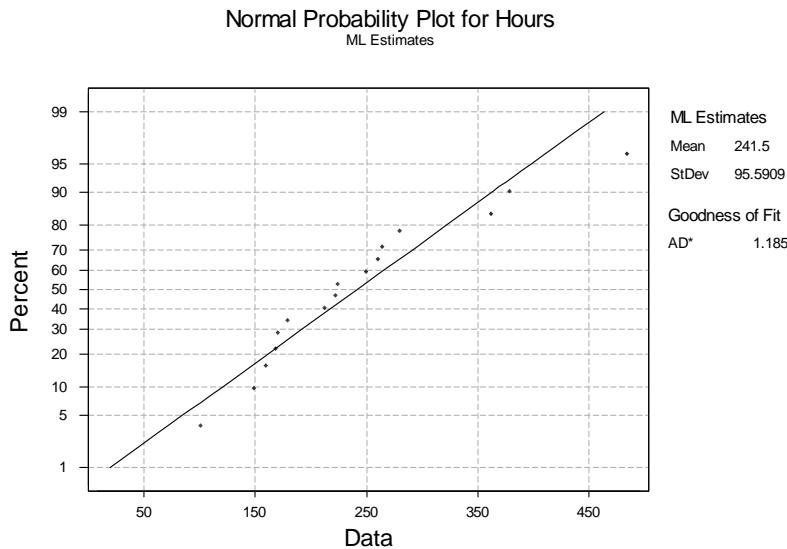

$$\text{The 95\% confidence interval is } \bar{y} - t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} \leq \mu \leq \bar{y} + t_{\alpha/2, n-1} \frac{S}{\sqrt{n}}$$

$$241.50 - (2.131) \left(\frac{98.73}{\sqrt{16}} \right) \leq \mu \leq 241.50 + (2.131) \left(\frac{98.73}{\sqrt{16}} \right)$$

$$188.9 \leq \mu \leq 294.1$$

2-8 Reconsider the repair time data in Problem 2-7. Can repair time, in your opinion, be adequately modeled by a normal distribution?

The normal probability plot below does not reveal any serious problem with the normality assumption.

2-9 Two machines are used for filling plastic bottles with a net volume of 16.0 ounces. The filling processes can be assumed to be normal, with standard deviation of $\sigma_1 = 0.015$ and $\sigma_2 = 0.018$. The quality engineering department suspects that both machines fill to the same net volume, whether or not this volume is 16.0 ounces. An experiment is performed by taking a random sample from the output of each machine.

Machine 1		Machine 2	
16.03	16.01	16.02	16.03
16.04	15.96	15.97	16.04
16.05	15.98	15.96	16.02
16.05	16.02	16.01	16.01
16.02	15.99	15.99	16.00

(a) State the hypotheses that should be tested in this experiment.

$$H_0: \mu_1 = \mu_2 \quad H_1: \mu_1 \neq \mu_2$$

(b) Test these hypotheses using $\alpha=0.05$. What are your conclusions?

$$\bar{y}_1 = 16.015 \quad \bar{y}_2 = 16.005$$

$$\sigma_1 = 0.015 \quad \sigma_2 = 0.018$$

$$n_1 = 10 \quad n_2 = 10$$

$$z_o = \frac{\bar{y}_1 - \bar{y}_2}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}} = \frac{16.015 - 16.018}{\sqrt{\frac{0.015^2}{10} + \frac{0.018^2}{10}}} = 1.35$$

$$z_{0.025} = 1.96; \text{ do not reject}$$

(c) What is the P -value for the test? $P = 0.1770$

(d) Find a 95 percent confidence interval on the difference in the mean fill volume for the two machines.

The 95% confidence interval is

$$\begin{aligned}\bar{y}_1 - \bar{y}_2 - z_{\alpha/2} \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} &\leq \mu_1 - \mu_2 \leq \bar{y}_1 - \bar{y}_2 + z_{\alpha/2} \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} \\ (16.015 - 16.005) - (19.6) \sqrt{\frac{0.015^2}{10} + \frac{0.018^2}{10}} &\leq \mu_1 - \mu_2 \leq (16.015 - 16.005) + (19.6) \sqrt{\frac{0.015^2}{10} + \frac{0.018^2}{10}} \\ -0.0045 &\leq \mu_1 - \mu_2 \leq 0.0245\end{aligned}$$

2-10 Two types of plastic are suitable for use by an electronic calculator manufacturer. The breaking strength of this plastic is important. It is known that $\sigma_1 = \sigma_2 = 1.0$ psi. From random samples of $n_1 = 10$ and $n_2 = 12$ we obtain $\bar{y}_1 = 162.5$ and $\bar{y}_2 = 155.0$. The company will not adopt plastic 1 unless its breaking strength exceeds that of plastic 2 by at least 10 psi. Based on the sample information, should they use plastic 1? In answering this question, set up and test appropriate hypotheses using $\alpha = 0.01$. Construct a 99 percent confidence interval on the true mean difference in breaking strength.

$$H_0: \mu_1 - \mu_2 = 10 \quad H_1: \mu_1 - \mu_2 > 10$$

$$\bar{y}_1 = 162.5 \quad \bar{y}_2 = 155.0$$

$$\sigma_1 = 1 \quad \sigma_2 = 1$$

$$n_1 = 10 \quad n_2 = 10$$

$$z_o = \frac{\bar{y}_1 - \bar{y}_2 - 10}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}} = \frac{162.5 - 155.0 - 10}{\sqrt{\frac{1^2}{10} + \frac{1^2}{12}}} = -5.85$$

$$z_{0.01} = 2.225; \text{ do not reject}$$

The 99 percent confidence interval is

$$\begin{aligned}\bar{y}_1 - \bar{y}_2 - z_{\alpha/2} \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} &\leq \mu_1 - \mu_2 \leq \bar{y}_1 - \bar{y}_2 + z_{\alpha/2} \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} \\ (162.5 - 155.0) - (2.575) \sqrt{\frac{1^2}{10} + \frac{1^2}{12}} &\leq \mu_1 - \mu_2 \leq (162.5 - 155.0) + (2.575) \sqrt{\frac{1^2}{10} + \frac{1^2}{12}} \\ 6.40 &\leq \mu_1 - \mu_2 \leq 8.60\end{aligned}$$

2-11 The following are the burning times (in minutes) of chemical flares of two different formulations. The design engineers are interested in both the means and variance of the burning times.

Type 1		Type 2	
65	82	64	56
81	67	71	69
57	59	83	74
66	75	59	82
82	70	65	79

- (a) Test the hypotheses that the two variances are equal. Use $\alpha = 0.05$.

$$\begin{aligned}
 H_0: \sigma_1^2 &= \sigma_2^2 & S_1 &= 9.264 \\
 H_1: \sigma_1^2 &\neq \sigma_2^2 & S_2 &= 9.367 \\
 F_0 &= \frac{S_1^2}{S_2^2} = \frac{85.82}{87.73} = 0.98 \\
 F_{0.025,9,9} &= 4.03 & F_{0.975,9,9} &= \frac{1}{F_{0.025,9,9}} = \frac{1}{4.03} = 0.248 \text{ Do not reject.}
 \end{aligned}$$

- (b) Using the results of (a), test the hypotheses that the mean burning times are equal. Use $\alpha = 0.05$. What is the P -value for this test?

$$\begin{aligned}
 S_p^2 &= \frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{n_1 + n_2 - 2} = \frac{1561.95}{18} = 86.775 \\
 S_p &= 9.32 \\
 t_0 &= \frac{\bar{y}_1 - \bar{y}_2}{S_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} = \frac{70.4 - 70.2}{9.32 \sqrt{\frac{1}{10} + \frac{1}{10}}} = 0.048 \\
 t_{0.025,18} &= 2.101 \text{ Do not reject.}
 \end{aligned}$$

From the computer output, $t=0.05$; do not reject. Also from the computer output $P=0.96$

Minitab Output

Two Sample T-Test and Confidence Interval

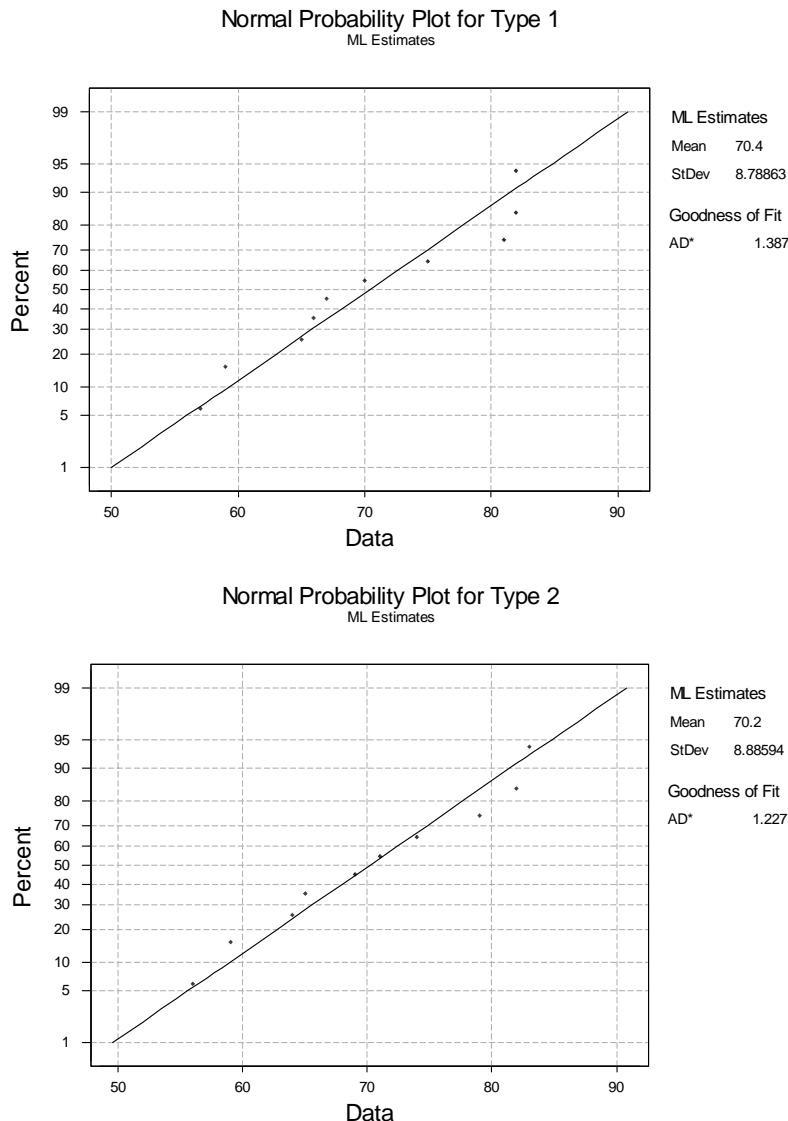

Two sample T for Type 1 vs Type 2

	N	Mean	StDev	SE Mean
Type 1	10	70.40	9.26	2.9
Type 2	10	70.20	9.37	3.0

95% CI for mu Type 1 - mu Type 2: (-8.6, 9.0)
 T-Test mu Type 1 = mu Type 2 (vs not =): T = 0.05 P = 0.96 DF = 18
 Both use Pooled StDev = 9.32

- (c) Discuss the role of the normality assumption in this problem. Check the assumption of normality for both types of flares.

The assumption of normality is required in the theoretical development of the t -test. However, moderate departure from normality has little impact on the performance of the t -test. The normality assumption is more important for the test on the equality of the two variances. An indication of nonnormality would be of concern here. The normal probability plots shown below indicate that burning time for both formulations follow the normal distribution.

2-12 An article in *Solid State Technology*, "Orthogonal Design of Process Optimization and Its Application to Plasma Etching" by G.Z. Yin and D.W. Jillie (May, 1987) describes an experiment to determine the effect of C_2F_6 flow rate on the uniformity of the etch on a silicon wafer used in integrated circuit manufacturing. Data for two flow rates are as follows:

C_2F_6 (SCCM)	Uniformity Observation					
	1	2	3	4	5	6
125	2.7	4.6	2.6	3.0	3.2	3.8
200	4.6	3.4	2.9	3.5	4.1	5.1

(a) Does the C_2F_6 flow rate affect average etch uniformity? Use $\alpha = 0.05$.

No, C_2F_6 flow rate does not affect average etch uniformity.

Minitab Output

Two Sample T-Test and Confidence Interval					
Two sample T for Uniformity					
Flow Rat	N	Mean	StDev	SE Mean	
125	6	3.317	0.760	0.31	
200	6	3.933	0.821	0.34	
95% CI for mu (125) - mu (200): (-1.63, 0.40)					
T-Test mu (125) = mu (200) (vs not =): T = -1.35 P = 0.21 DF = 10					
Both use Pooled StDev = 0.791					

(b) What is the P -value for the test in part (a)? From the computer printout, $P=0.21$

(c) Does the C_2F_6 flow rate affect the wafer-to-wafer variability in etch uniformity? Use $\alpha=0.05$.

$$H_0: \sigma_1^2 = \sigma_2^2$$

$$H_1: \sigma_1^2 \neq \sigma_2^2$$

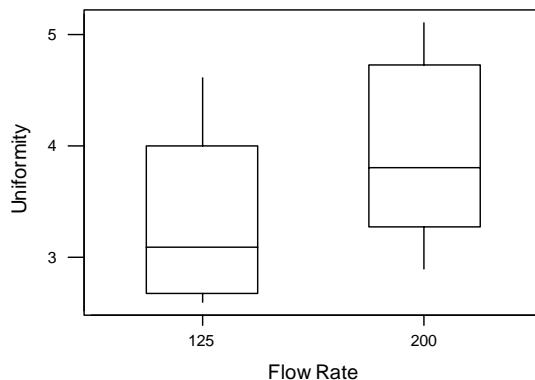

$$F_{0.05,5,5} = 5.05$$

$$F_0 = \frac{0.5776}{0.6724} = 0.86$$

Do not reject; C_2F_6 flow rate does not affect wafer-to-wafer variability.

(d) Draw box plots to assist in the interpretation of the data from this experiment.

The box plots shown below indicate that there is little difference in uniformity at the two gas flow rates. Any observed difference is not statistically significant. See the t -test in part (a).

2-13 A new filtering device is installed in a chemical unit. Before its installation, a random sample yielded the following information about the percentage of impurity: $\bar{y}_1 = 12.5$, $S_1^2 = 101.17$, and $n_1 = 8$. After installation, a random sample yielded $\bar{y}_2 = 10.2$, $S_2^2 = 94.73$, $n_2 = 9$.

(a) Can you conclude that the two variances are equal? Use $\alpha=0.05$.

$$H_0 : \sigma_1^2 = \sigma_2^2$$

$$H_1 : \sigma_1^2 \neq \sigma_2^2$$

$$F_{0.025,7,8} = 4.53$$

$$F_0 = \frac{S_1^2}{S_2^2} = \frac{101.17}{94.73} = 1.07$$

Do Not Reject. Assume that the variances are equal.

- (b) Has the filtering device reduced the percentage of impurity significantly? Use $\alpha = 0.05$.

$$H_0 : \mu_1 = \mu_2$$

$$H_1 : \mu_1 \neq \mu_2$$

$$S_p^2 = \frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{n_1 + n_2 - 2} = \frac{(8 - 1)(101.17) + (9 - 1)(94.73)}{8 + 9 - 2} = 97.74$$

$$S_p = 9.89$$

$$t_0 = \frac{\bar{y}_1 - \bar{y}_2}{S_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} = \frac{12.5 - 10.2}{9.89 \sqrt{\frac{1}{8} + \frac{1}{9}}} = 0.479$$

$$t_{0.05,15} = 1.753$$

Do not reject. There is no evidence to indicate that the new filtering device has affected the mean

2-14 Photoresist is a light-sensitive material applied to semiconductor wafers so that the circuit pattern can be imaged on to the wafer. After application, the coated wafers are baked to remove the solvent in the photoresist mixture and to harden the resist. Here are measurements of photoresist thickness (in kÅ) for eight wafers baked at two different temperatures. Assume that all of the runs were made in random order.

95 °C	100 °C
11.176	5.263
7.089	6.748
8.097	7.461
11.739	7.015
11.291	8.133
10.759	7.418
6.467	3.772
8.315	8.963

- (a) Is there evidence to support the claim that the higher baking temperature results in wafers with a lower mean photoresist thickness? Use $\alpha = 0.05$.

$$H_0: \mu_1 = \mu_2$$

$$H_1: \mu_1 \neq \mu_2$$

$$S_p^2 = \frac{(n_1-1)S_1^2 + (n_2-1)S_2^2}{n_1+n_2-2} = \frac{(8-1)(4.41) + (8-1)(2.54)}{8+8-2} = 3.48$$

$$S_p = 1.86$$

$$t_0 = \frac{\bar{y}_1 - \bar{y}_2}{S_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} = \frac{9.37 - 6.89}{1.86 \sqrt{\frac{1}{8} + \frac{1}{8}}} = 2.65$$

$$t_{0.05,14} = 1.761$$

Since $t_{0.05,14} = 1.761$, reject H_0 . There appears to be a lower mean thickness at the higher temperature. This is also seen in the computer output.

Minitab Output

Two-Sample T-Test and CI: Thickness, Temp

Two-sample T for Thickness

Temp	N	Mean	StDev	SE Mean
95	8	9.37	2.10	0.74
100	8	6.89	1.60	0.56

Difference = mu (95) - mu (100)

Estimate for difference: 2.475

95% CI for difference: (0.476, 4.474)

T-Test of difference = 0 (vs not =): T-Value = 2.65 P-Value = 0.019 DF = 14

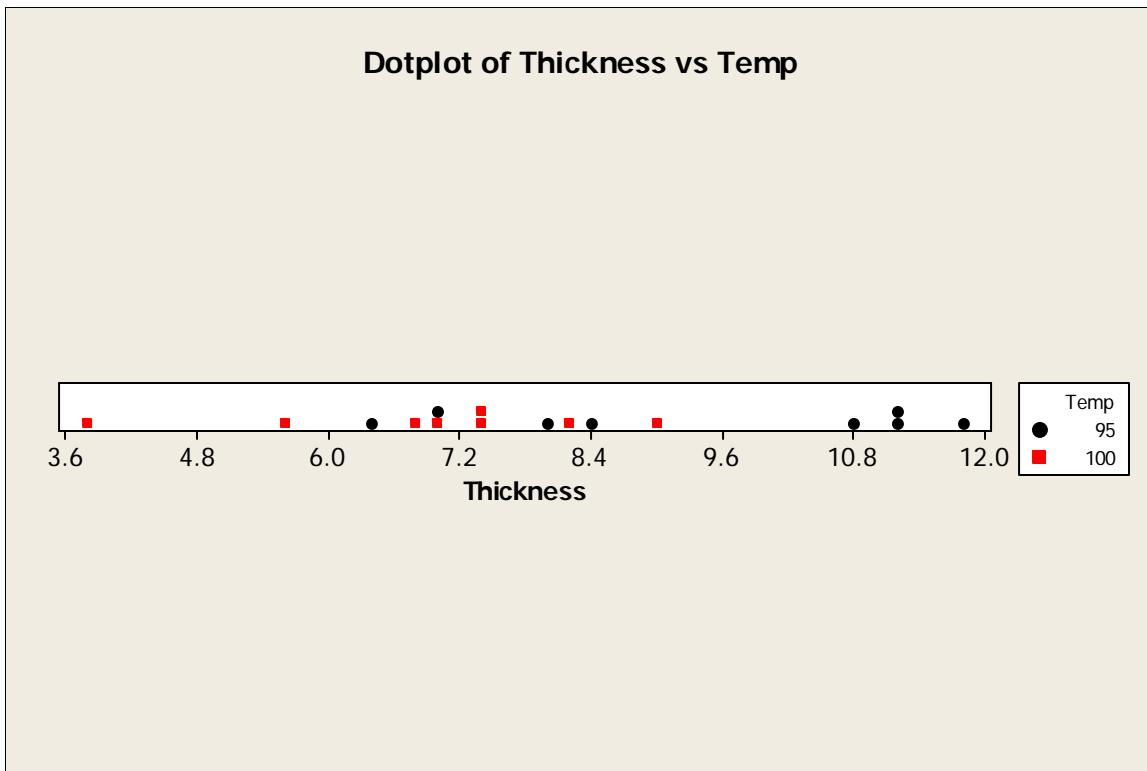

Both use Pooled StDev = 1.86

(b) What is the P -value for the test conducted in part (a)? $P = 0.019$

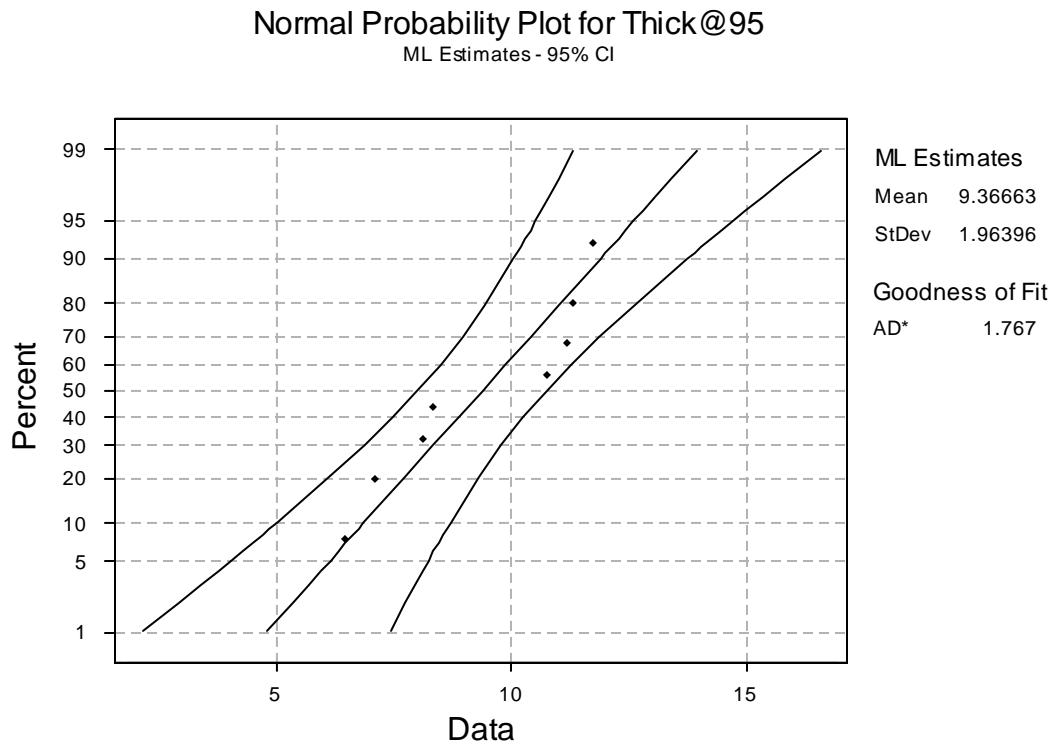

(c) Find a 95% confidence interval on the difference in means. Provide a practical interpretation of this interval.

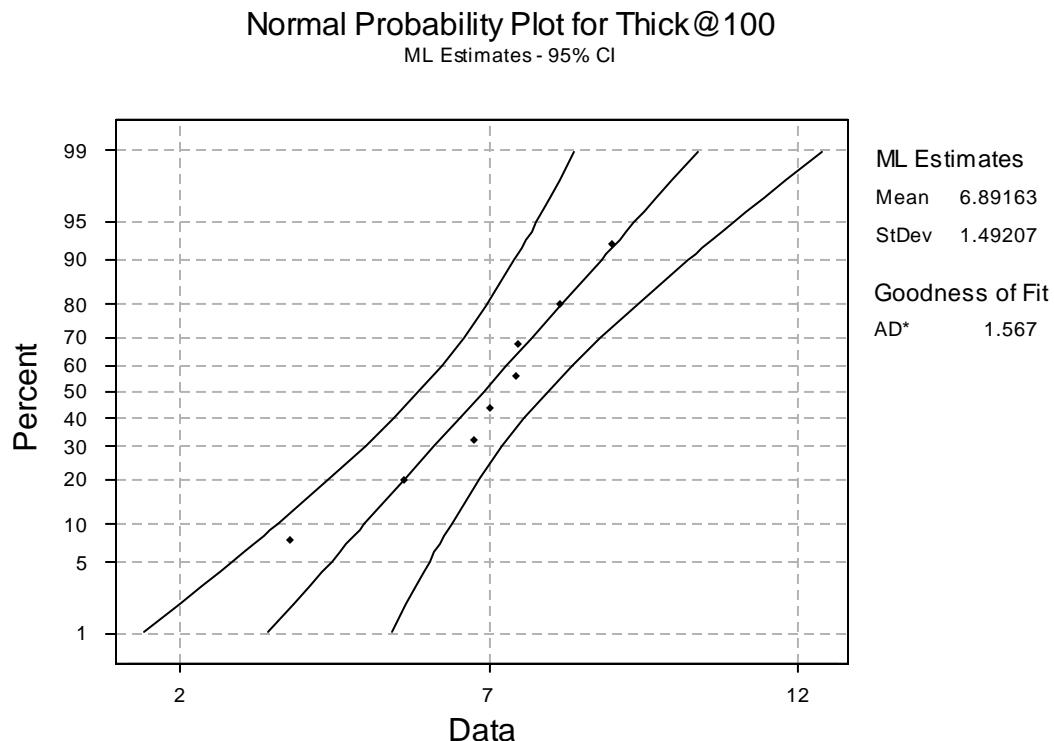

From the computer output the 95% confidence interval is $0.476 \leq \mu_1 - \mu_2 \leq 4.474$. This confidence interval does not include 0 in it, therefore there is a difference in the two temperatures on the thickness of the photo resist.

(d) Draw dot diagrams to assist in interpreting the results from this experiment.

(e) Check the assumption of normality of the photoresist thickness.

There are no significant deviations from the normality assumptions.

- (f) Find the power of this test for detecting an actual difference in means of $2.5 \text{ k}\text{\AA}$.

Minitab Output

      2.5       8     0.7056
```

- (g) What sample size would be necessary to detect an actual difference in means of $1.5 \text{ k}\text{\AA}$ with a power of at least 0.9?

Minitab Output

Power and Sample Size

```
2-Sample t Test

Testing mean 1 = mean 2 (versus not =)
Calculating power for mean 1 = mean 2 + difference
Alpha = 0.05 Sigma = 1.86

      Sample   Target   Actual
Difference   Size   Power   Power
      1.5       34     0.9000  0.9060
```

This result makes intuitive sense. More samples are needed to detect a smaller difference.

2-15 Front housings for cell phones are manufactured in an injection molding process. The time the part is allowed to cool in the mold before removal is thought to influence the occurrence of a particularly troublesome cosmetic defect, flow lines, in the finished housing. After manufacturing, the housings are inspected visually and assigned a score between 1 and 10 based on their appearance, with 10 corresponding to a perfect part and 1 corresponding to a completely defective part. An experiment was conducted using two cool-down times, 10 seconds and 20 seconds, and 20 housings were evaluated at each level of cool-down time. The data are shown below.

	10 Seconds	20 Seconds	
1	3	7	6
2	6	8	9
1	5	5	5
3	3	9	7
5	2	5	4
1	1	8	6
5	6	6	8
2	8	4	5
3	2	6	8
5	3	7	7

- (a) Is there evidence to support the claim that the longer cool-down time results in fewer appearance defects? Use $\alpha = 0.05$.

Minitab Output

Two-Sample T-Test and CI: 10 seconds, 20 seconds

Two-sample T for 10 seconds vs 20 seconds

N	Mean	StDev	SE Mean	
10 secon	20	3.35	2.01	0.45
20 secon	20	6.50	1.54	0.34

Difference = mu 10 seconds - mu 20 seconds

Estimate for difference: -3.150

95% CI for difference: (-4.295, -2.005)

T-Test of difference = 0 (vs not =): T-Value = -5.57 P-Value = 0.000 DF = 38

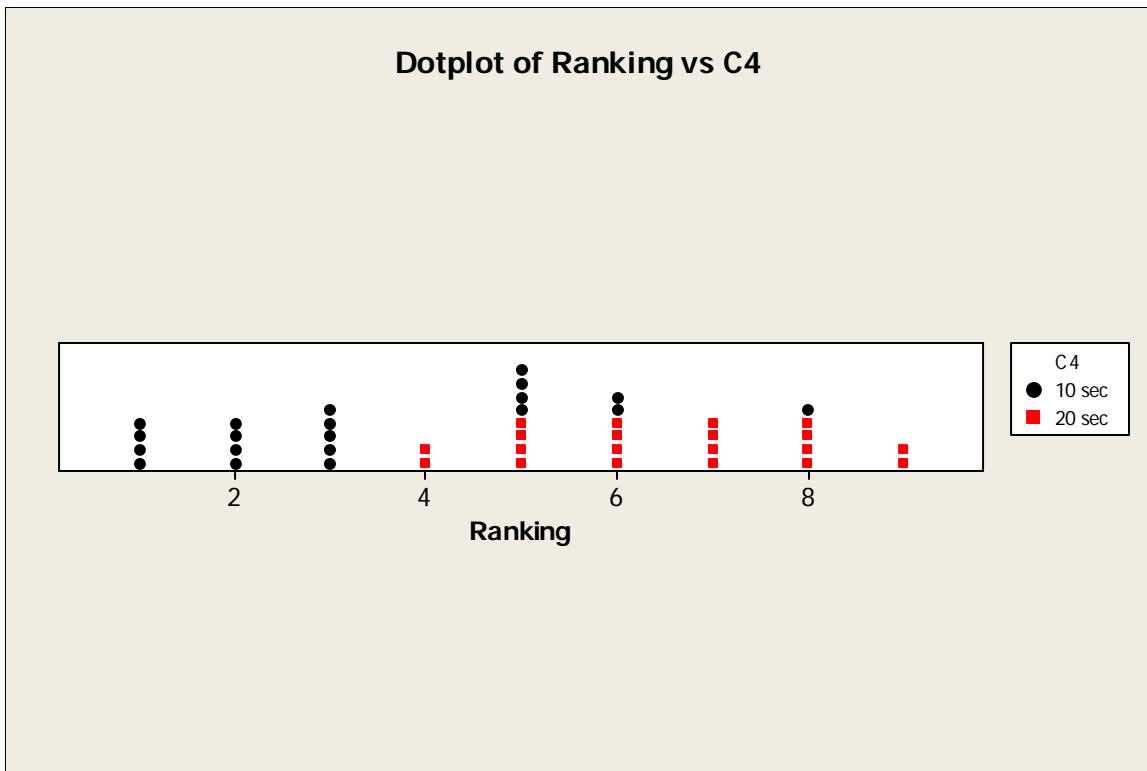

Both use Pooled StDev = 1.79

- (b) What is the P -value for the test conducted in part (a)? From the Minitab output, $P = 0.000$

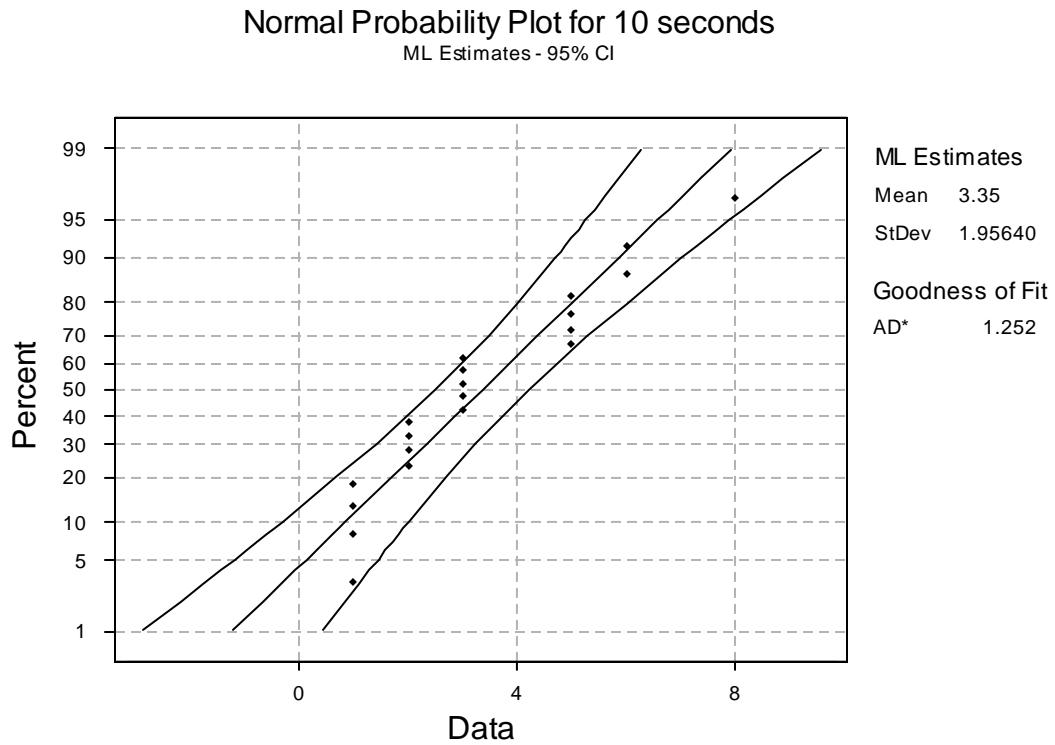

- (c) Find a 95% confidence interval on the difference in means. Provide a practical interpretation of this interval.

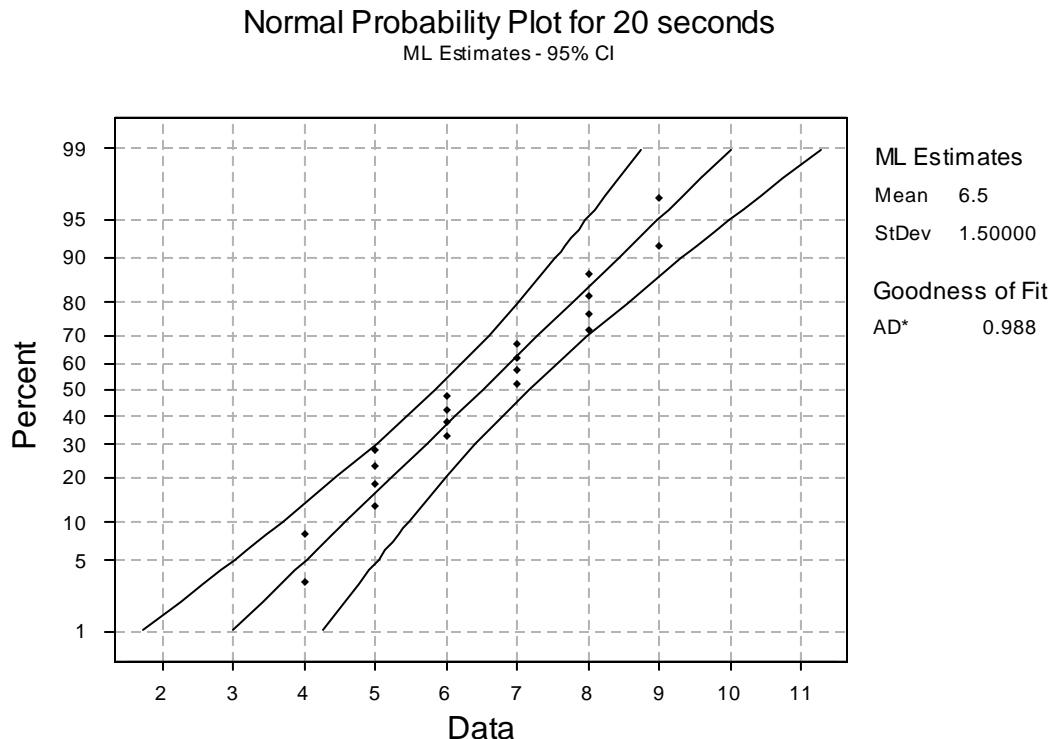

From the computer output, $-4.295 \leq \mu_1 - \mu_2 \leq -2.005$. This interval does not contain 0. The two samples are different. The 20 second cooling time gives a cosmetically better housing.

- (d) Draw dot diagrams to assist in interpreting the results from this experiment.

- (e) Check the assumption of normality for the data from this experiment.

There are no significant departures from normality.

2-16 Twenty observations on etch uniformity on silicon wafers are taken during a qualification experiment for a plasma etcher. The data are as follows:

5.34	6.65	4.76	5.98	7.25
6.00	7.55	5.54	5.62	6.21
5.97	7.35	5.44	4.39	4.98
5.25	6.35	4.61	6.00	5.32

- (a) Construct a 95 percent confidence interval estimate of σ^2 .

$$\begin{aligned} \frac{(n-1)S^2}{\chi_{\alpha/2,n-1}^2} &\leq \sigma^2 \leq \frac{(n-1)S^2}{\chi_{(1-\alpha/2),n-1}^2} \\ \frac{(20-1)(0.88907)^2}{32.852} &\leq \sigma^2 \leq \frac{(20-1)(0.88907)^2}{8.907} \\ 0.457 \leq \sigma^2 &\leq 1.686 \end{aligned}$$

- (b) Test the hypothesis that $\sigma^2 = 1.0$. Use $\alpha = 0.05$. What are your conclusions?

$$H_0: \sigma^2 = 1$$

$$H_1: \sigma^2 \neq 1$$

$$\chi_0^2 = \frac{SS}{\sigma_0^2} = 15.019$$

$$\chi^2_{0.025,19} = 32.852 \quad \chi^2_{0.975,19} = 8.907$$

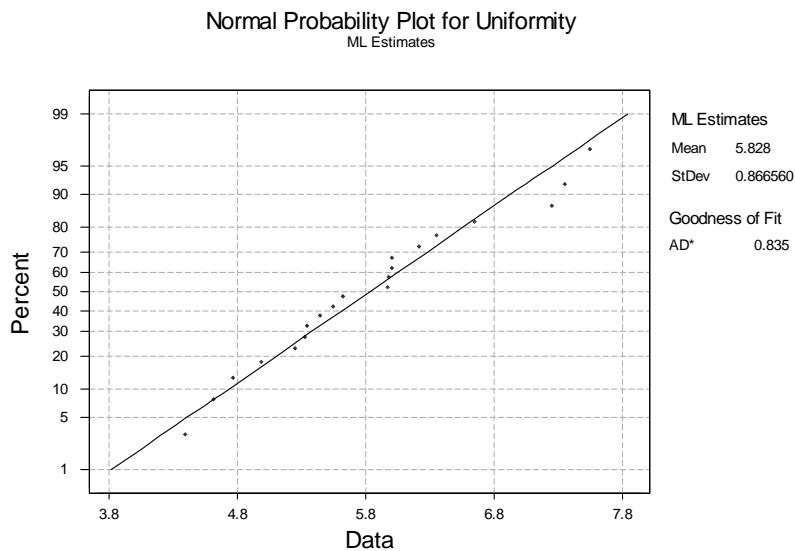

Do not reject. There is no evidence to indicate that $\sigma^2 \neq 1$

- (c) Discuss the normality assumption and its role in this problem.

The normality assumption is much more important when analyzing variances than when analyzing means. A moderate departure from normality could cause problems with both statistical tests and confidence intervals. Specifically, it will cause the reported significance levels to be incorrect.

- (d) Check normality by constructing a normal probability plot. What are your conclusions?

The normal probability plot indicates that there is not any serious problem with the normality assumption.

- 2-17** The diameter of a ball bearing was measured by 12 inspectors, each using two different kinds of calipers. The results were:

Inspector	Caliper 1	Caliper 2	Difference	Difference ²
1	0.265	0.264	.001	.000001
2	0.265	0.265	.000	0
3	0.266	0.264	.002	.000004
4	0.267	0.266	.001	.000001
5	0.267	0.267	.000	0
6	0.265	0.268	-.003	.000009
7	0.267	0.264	.003	.000009
8	0.267	0.265	.002	.000004
9	0.265	0.265	.000	0
10	0.268	0.267	.001	.000001
11	0.268	0.268	.000	0
12	0.265	0.269	-.004	.000016
			$\sum = 0.003$	$\sum = 0.000045$

- (a) Is there a significant difference between the means of the population of measurements represented by the two samples? Use $\alpha = 0.05$.

$$\begin{array}{ll} H_0: \mu_1 = \mu_2 & \text{or equivalently } H_0: \mu_d = 0 \\ H_1: \mu_1 \neq \mu_2 & H_1: \mu_d \neq 0 \end{array}$$

Minitab Output

- (b) Find the P -value for the test in part (a). $P=0.674$

- (c) Construct a 95 percent confidence interval on the difference in the mean diameter measurements for the two types of calipers.

$$\begin{aligned} \bar{d} - t_{\alpha/2, n-1} \frac{s_d}{\sqrt{n}} &\leq \mu_d (= \mu_1 - \mu_2) \leq \bar{d} + t_{\alpha/2, n-1} \frac{s_d}{\sqrt{n}} \\ 0.00025 - 2.201 \frac{0.002}{\sqrt{12}} &\leq \mu_d \leq 0.00025 + 2.201 \frac{0.002}{\sqrt{12}} \\ -0.00102 &\leq \mu_d \leq 0.00152 \end{aligned}$$

2-18 An article in the *Journal of Strain Analysis* (vol.18, no. 2, 1983) compares several procedures for predicting the shear strength for steel plate girders. Data for nine girders in the form of the ratio of predicted to observed load for two of these procedures, the Karlsruhe and Lehigh methods, are as follows:

Girder	Karlsruhe Method	Lehigh Method	Difference	Difference^2
S1/1	1.186	1.061	0.125	0.015625
S2/1	1.151	0.992	0.159	0.025281
S3/1	1.322	1.063	0.259	0.067081
S4/1	1.339	1.062	0.277	0.076729
S5/1	1.200	1.065	0.135	0.018225
S2/1	1.402	1.178	0.224	0.050176
S2/2	1.365	1.037	0.328	0.107584
S2/3	1.537	1.086	0.451	0.203401
S2/4	1.559	1.052	0.507	0.257049
	Sum =	2.465	0.821151	
	Average =	0.274		

- (a) Is there any evidence to support a claim that there is a difference in mean performance between the two methods? Use $\alpha = 0.05$.

$$\begin{array}{ll} H_0: \mu_1 = \mu_2 & \text{or equivalently } H_0: \mu_d = 0 \\ H_1: \mu_1 \neq \mu_2 & H_1: \mu_d \neq 0 \end{array}$$

$$\bar{d} = \frac{1}{n} \sum_{i=1}^n d_i = \frac{1}{9}(2.465) = 0.274$$

$$s_d = \left[\frac{\sum_{i=1}^n d_i^2 - \frac{1}{n} \left(\sum_{i=1}^n d_i \right)^2}{n-1} \right]^{\frac{1}{2}} = \left[\frac{0.821151 - \frac{1}{9}(2.465)^2}{9-1} \right]^{\frac{1}{2}} = 0.135$$

$$t_0 = \frac{\bar{d}}{\frac{s_d}{\sqrt{n}}} = \frac{0.274}{\frac{0.135}{\sqrt{9}}} = 6.08$$

$t_{\alpha/2, n-1} = t_{0.025, 9} = 2.306$, reject the null hypothesis.

Minitab Output

Paired T-Test and Confidence Interval

Paired T for Karlsruhe - Lehigh

	N	Mean	StDev	SE Mean
Karlsruhe	9	1.3401	0.1460	0.0487

Difference	9	0.2739	0.1351	0.0450

95% CI for mean difference: (0.1700, 0.3777)

T-Test of mean difference = 0 (vs not = 0): T-Value = 6.08 P-Value = 0.000

(b) What is the P -value for the test in part (a)? $P=0.0002$

(c) Construct a 95 percent confidence interval for the difference in mean predicted to observed load.

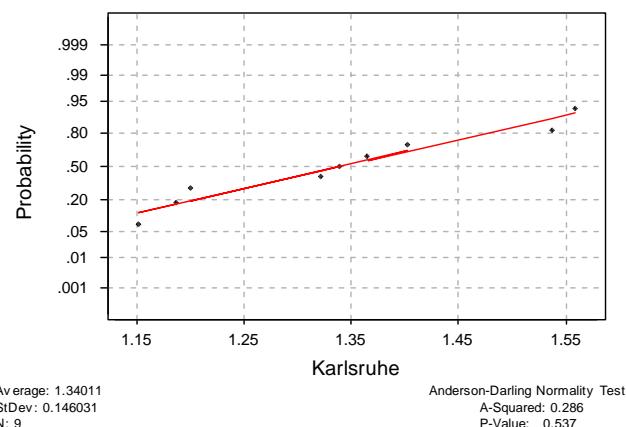

$$\bar{d} - t_{\alpha/2, n-1} \frac{s_d}{\sqrt{n}} \leq \mu_d \leq \bar{d} + t_{\alpha/2, n-1} \frac{s_d}{\sqrt{n}}$$

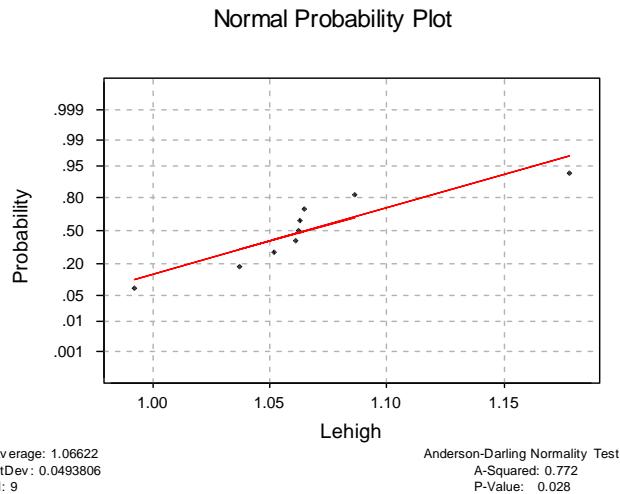

$$0.274 - 2.306 \frac{0.135}{\sqrt{9}} \leq \mu_d \leq 0.274 + 2.306 \frac{0.135}{\sqrt{9}}$$

$$0.17023 \leq \mu_d \leq 0.37777$$

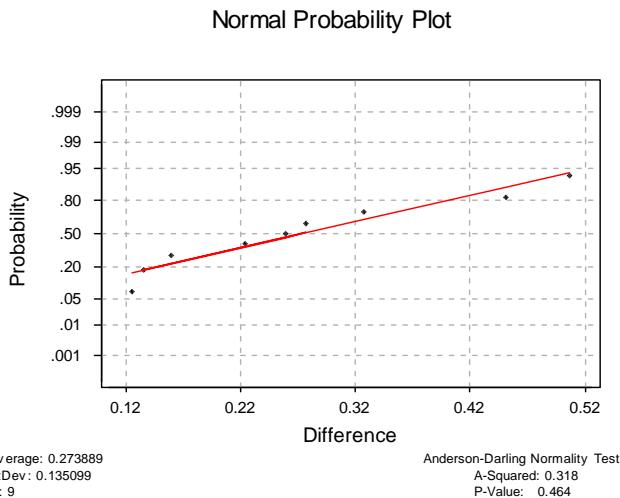

(d) Investigate the normality assumption for both samples.

Normal Probability Plot

- (e) Investigate the normality assumption for the difference in ratios for the two methods.

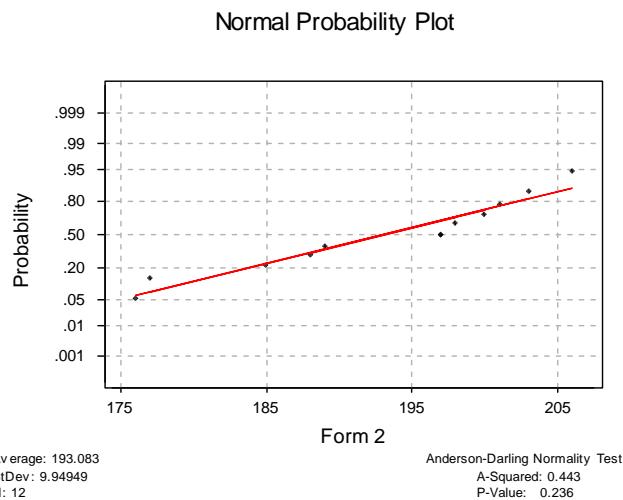

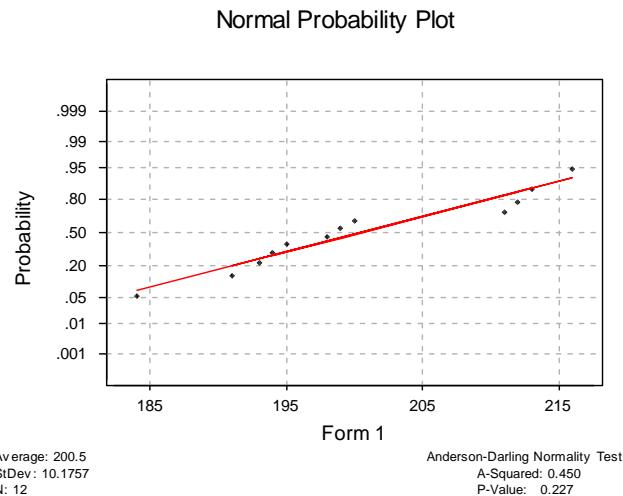

- (f) Discuss the role of the normality assumption in the paired t -test.

As in any t -test, the assumption of normality is of only moderate importance. In the paired t -test, the assumption of normality applies to the distribution of the differences. That is, the individual sample measurements do not have to be normally distributed, only their difference.

2-19 The deflection temperature under load for two different formulations of ABS plastic pipe is being studied. Two samples of 12 observations each are prepared using each formulation, and the deflection temperatures (in °F) are reported below:

	Formulation 1			Formulation 2		
212	199	198	177	176	198	
194	213	216	197	185	188	
211	191	200	206	200	189	
193	195	184	201	197	203	

- (a) Construct normal probability plots for both samples. Do these plots support assumptions of normality and equal variance for both samples?

- (b) Do the data support the claim that the mean deflection temperature under load for formulation 1 exceeds that of formulation 2? Use $\alpha = 0.05$.

Minitab Output

95% CI for mu Form 1 - mu Form 2: (-1.1, 15.9)
T-Test mu Form 1 = mu Form 2 (vs >): T = 1.81   P = 0.042   DF = 22
Both use Pooled StDev = 10.1
```

- (c) What is the P -value for the test in part (a)? $P = 0.042$

- 2-20** Refer to the data in problem 2-19. Do the data support a claim that the mean deflection temperature under load for formulation 1 exceeds that of formulation 2 by at least 3 °F?

Yes, formulation 1 exceeds formulation 2 by at least 3 °F.

Minitab Output

Two-Sample T-Test and CI: Form1, Form2

Two-sample T for Form1 vs Form2

	N	Mean	StDev	SE Mean
Form1	12	200.5	10.2	2.9
Form2	12	193.08	9.95	2.9r

Difference = mu Form1 - mu Form2
Estimate for difference: 7.42
95% lower bound for difference: 0.36
T-Test of difference = 3 (vs >): T-Value = 1.08 P-Value = 0.147 DF = 22
Both use Pooled StDev = 10.1

- 2-21** In semiconductor manufacturing, wet chemical etching is often used to remove silicon from the backs of wafers prior to metalization. The etch rate is an important characteristic of this process. Two different etching solutions are being evaluated. Eight randomly selected wafers have been etched in each solution and the observed etch rates (in mils/min) are shown below:

Solution 1		Solution 2	
9.9	10.6	10.2	10.6
9.4	10.3	10.0	10.2
10.0	9.3	10.7	10.4
10.3	9.8	10.5	10.3

- (a) Do the data indicate that the claim that both solutions have the same mean etch rate is valid? Use $\alpha = 0.05$ and assume equal variances.

See the Minitab output below.

Minitab Output

Two Sample T-Test and Confidence Interval

Two sample T for Solution 1 vs Solution 2

	N	Mean	StDev	SE Mean
Solution 1	8	9.925	0.465	0.16
Solution 2	8	10.362	0.233	0.082

95% CI for mu Solution 1 - mu Solution 2: (-0.83, -0.043)
T-Test mu Solution 1 = mu Solution 2 (vs not =): T = -2.38 P = 0.032 DF = 14
Both use Pooled StDev = 0.368

- (b) Find a 95% confidence interval on the difference in mean etch rate.

From the Minitab output, -0.83 to -0.043.

- (c) Use normal probability plots to investigate the adequacy of the assumptions of normality and equal variances.

Both the normality and equality of variance assumptions are valid.

2-22 Two popular pain medications are being compared on the basis of the speed of absorption by the body. Specifically, tablet 1 is claimed to be absorbed twice as fast as tablet 2. Assume that σ_1^2 and σ_2^2 are known. Develop a test statistic for

$$\begin{aligned} H_0: 2\mu_1 &= \mu_2 \\ H_1: 2\mu_1 &\neq \mu_2 \end{aligned}$$

$2\bar{y}_1 - \bar{y}_2 \sim N\left(2\mu_1 - \mu_2, \frac{4\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}\right)$, assuming that the data is normally distributed.

The test statistic is: $z_o = \frac{2\bar{y}_1 - \bar{y}_2}{\sqrt{\frac{4\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}}$, reject if $|z_o| > z_{\alpha/2}$

2-23 Suppose we are testing

$$\begin{aligned} H_0: \mu_1 &= \mu_2 \\ H_1: \mu_1 &\neq \mu_2 \end{aligned}$$

where σ_1^2 and σ_2^2 are known. Our sampling resources are constrained such that $n_1 + n_2 = N$. How should we allocate the N observations between the two populations to obtain the most powerful test?

The most powerful test is attained by the n_1 and n_2 that maximize z_o for given $\bar{y}_1 - \bar{y}_2$.

Thus, we chose n_1 and n_2 to $\max z_o = \frac{\bar{y}_1 - \bar{y}_2}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}}$, subject to $n_1 + n_2 = N$.

This is equivalent to $\min L = \frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2} = \frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{N-n_1}$, subject to $n_1 + n_2 = N$.

Now $\frac{dL}{dn_1} = \frac{-\sigma_1^2}{n_1^2} + \frac{\sigma_2^2}{(N-n_1)^2} = 0$, implies that $n_1 / n_2 = \sigma_1 / \sigma_2$.

Thus n_1 and n_2 are assigned proportionally to the ratio of the standard deviations. This has intuitive appeal, as it allocates more observations to the population with the greatest variability.

2-24 Develop Equation 2-46 for a $100(1 - \alpha)$ percent confidence interval for the variance of a normal distribution.

$\frac{SS}{\sigma^2} \sim \chi_{n-1}^2$. Thus, $P\left\{\chi_{\frac{n-\alpha}{2}, n-1}^2 \leq \frac{SS}{\sigma^2} \leq \chi_{\frac{\alpha}{2}, n-1}^2\right\} = 1 - \alpha$. Therefore,

$$P\left\{\frac{SS}{\chi_{\frac{\alpha}{2}, n-1}^2} \leq \sigma^2 \leq \frac{SS}{\chi_{\frac{n-\alpha}{2}, n-1}^2}\right\} = 1 - \alpha,$$

so $\left[\frac{SS}{\chi_{\frac{\alpha}{2}, n-1}^2}, \frac{SS}{\chi_{\frac{n-\alpha}{2}, n-1}^2}\right]$ is the $100(1 - \alpha)\%$ confidence interval on σ^2 .

2-25 Develop Equation 2-50 for a $100(1 - \alpha)$ percent confidence interval for the ratio σ_1^2 / σ_2^2 , where σ_1^2 and σ_2^2 are the variances of two normal distributions.

$$\frac{S_2^2 / \sigma_2^2}{S_1^2 / \sigma_1^2} \sim F_{n_2-1, n_1-1}$$

$$P\left\{F_{1-\alpha/2, n_2-1, n_1-1} \leq \frac{S_2^2 / \sigma_2^2}{S_1^2 / \sigma_1^2} \leq F_{\alpha/2, n_2-1, n_1-1}\right\} = 1 - \alpha \text{ or}$$

$$P\left\{\frac{S_1^2}{S_2^2} F_{1-\alpha/2, n_2-1, n_1-1} \leq \frac{\sigma_1^2}{\sigma_2^2} \leq \frac{S_1^2}{S_2^2} F_{\alpha/2, n_2-1, n_1-1}\right\} = 1 - \alpha$$

2-26 Develop an equation for finding a $100(1 - \alpha)$ percent confidence interval on the difference in the means of two normal distributions where $\sigma_1^2 \neq \sigma_2^2$. Apply your equation to the portland cement experiment data, and find a 95% confidence interval.

$$\frac{(\bar{y}_1 - \bar{y}_2) - (\mu_1 - \mu_2)}{\sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}} \sim t_{\alpha/2, v}$$

$$t_{\alpha/2, v} \sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}} \leq (\bar{y}_1 - \bar{y}_2) - (\mu_1 - \mu_2) \leq t_{\alpha/2, v} \sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}$$

$$(\bar{y}_1 - \bar{y}_2) - t_{\alpha/2, v} \sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}} \leq (\mu_1 - \mu_2) \leq (\bar{y}_1 - \bar{y}_2) + t_{\alpha/2, v} \sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}$$

where $v = \frac{\left(\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}\right)^2}{\left(\frac{S_1^2}{n_1}\right)^2 + \left(\frac{S_2^2}{n_2}\right)^2}$

$$v = \frac{\left(\frac{0.100138}{10} + \frac{0.0614622}{10}\right)^2}{\left(\frac{0.100138}{10}\right)^2 + \left(\frac{0.0614622}{10}\right)^2} = 17.024 \approx 17$$

Using the data from Table 2-1

$$\begin{aligned} n_1 &= 10 & n_2 &= 10 \\ \bar{y}_1 &= 16.764 & \bar{y}_2 &= 17.343 \\ S_1^2 &= 0.100138 & S_2^2 &= 0.0614622 \end{aligned}$$

$$(16.764 - 17.343) - 2.110 \sqrt{\frac{0.100138}{10} + \frac{0.0614622}{10}} \leq (\mu_1 - \mu_2) \leq (16.764 - 17.343) + 2.110 \sqrt{\frac{0.100138}{10} + \frac{0.0614622}{10}}$$

where $v = \frac{\left(\frac{0.100138}{10} + \frac{0.0614622}{10}\right)^2}{\left(\frac{0.100138}{10}\right)^2 + \left(\frac{0.0614622}{10}\right)^2} = 17.024 \approx 17$

$$-1.426 \leq (\mu_1 - \mu_2) \leq -0.889$$

This agrees with the result in Table 2-2.

2-27 Construct a data set for which the paired t -test statistic is very large, but for which the usual two-sample or pooled t -test statistic is small. In general, describe how you created the data. Does this give you any insight regarding how the paired t -test works?

```

These two sets of data were created by making the observation for *A* and *B* moderately different within each pair (or block), but making the observations between pairs very different. The fact that the difference between pairs is large makes the pooled estimate of the standard deviation large and the two-sample *t*-test statistic small. Therefore the fairly small difference between the means of the two treatments that is present when they are applied to the same experimental unit cannot be detected. Generally, if the blocks are very different, then this will occur. Blocking eliminates the variability associated with the nuisance variable that they represent.

- 2-28** Consider the experiment described in problem 2-11. If the mean burning times of the two flames differ by as much as 2 minutes, find the power of the test. What sample size would be required to detect an actual difference in mean burning time of 1 minute with a power of at least 0.90?

Minitab Output

- 2-29** Reconsider the bottle filling experiment described in Problem 2-9. Rework this problem assuming that the two population variances are unknown but equal.

Minitab Output

Two-Sample T-Test and CI: Machine 1, Machine 2

Two-sample T for Machine 1 vs Machine 2

	N	Mean	StDev	SE Mean
Machine 1	10	16.0150	0.0303	0.0096
Machine 2	10	16.0050	0.0255	0.0081

Difference = mu Machine 1 - mu Machine 2

Estimate for difference: 0.0100

95% CI for difference: (-0.0163, 0.0363)

T-Test of difference = 0 (vs not =): T-Value = 0.80 P-Value = 0.435 DF = 18
Both use Pooled StDev = 0.0280

The hypothesis test is the same: $H_0: \mu_1 = \mu_2$ $H_1: \mu_1 \neq \mu_2$

The conclusions are the same as Problem 2-9, do not reject H_0 . There is no difference in the machines.

The *P*-value for this analysis is 0.435.

The confidence interval is (-0.0163, 0.0363). This interval contains 0. There is no difference in machines.

2-29 Consider the data from problem 2-9. If the mean fill volume of the two machines differ by as much as 0.25 ounces, what is the power of the test used in problem 2-9? What sample size could result in a power of at least 0.9 if the actual difference in mean fill volume is 0.25 ounces?

Chapter 3

Experiments with a Single Factor: The Analysis of Variance Solutions

3-1 The tensile strength of portland cement is being studied. Four different mixing techniques can be used economically. The following data have been collected:

Mixing Technique	Tensile Strength (lb/in ²)			
1	3129	3000	2865	2890
2	3200	3300	2975	3150
3	2800	2900	2985	3050
4	2600	2700	2600	2765

- (a) Test the hypothesis that mixing techniques affect the strength of the cement. Use $\alpha = 0.05$.

Design Expert Output

Response: Tensile Strength in lb/in ²						
ANOVA for Selected Factorial Model						
Analysis of variance table [Partial sum of squares]						
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	4.897E+005	3	1.632E+005	12.73	0.0005	significant
A	4.897E+005	3	1.632E+005	12.73	0.0005	
Residual	1.539E+005	12	12825.69			
Lack of Fit	0.000	0				
Pure Error	1.539E+005	12	12825.69			
Cor Total	6.436E+005	15				

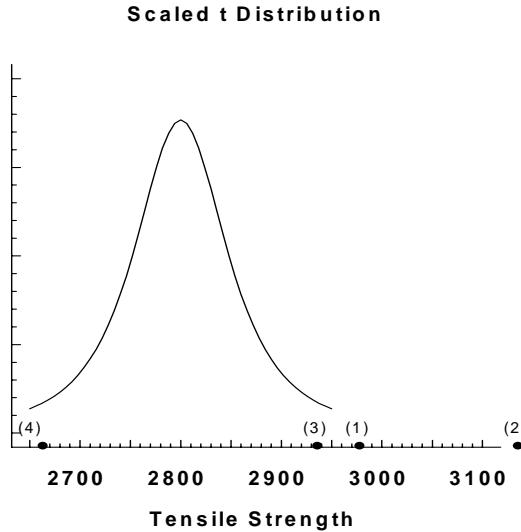

Treatment Means (Adjusted, If Necessary)						
Estimated Mean		Standard Error				
Treatment	Difference	DF	Error	t for H0 Coeff=0	Prob > t	
1-1	2971.00		56.63			
2-2	3156.25		56.63			
3-3	2933.75		56.63			
4-4	2666.25		56.63			

Treatment	Mean Difference	DF	Standard Error	t for H0 Coeff=0	Prob > t
1 vs 2	-185.25	1	80.08	-2.31	0.0392
1 vs 3	37.25	1	80.08	0.47	0.6501
1 vs 4	304.75	1	80.08	3.81	0.0025
2 vs 3	222.50	1	80.08	2.78	0.0167
2 vs 4	490.00	1	80.08	6.12	< 0.0001
3 vs 4	267.50	1	80.08	3.34	0.0059

The F -value is 12.73 with a corresponding P -value of .0005. Mixing technique has an effect.

- (b) Construct a graphical display as described in Section 3-5.3 to compare the mean tensile strengths for the four mixing techniques. What are your conclusions?

$$S_{\bar{y}_i} = \sqrt{\frac{MS_E}{n}} = \sqrt{\frac{12825.7}{4}} = 56.625$$

Based on examination of the plot, we would conclude that μ_1 and μ_3 are the same; that μ_4 differs from μ_1 and μ_3 , that μ_2 differs from μ_1 and μ_3 , and that μ_2 and μ_4 are different.

- (c) Use the Fisher LSD method with $\alpha=0.05$ to make comparisons between pairs of means.

$$LSD = t_{\frac{\alpha}{2}, N-a} \sqrt{\frac{2MS_E}{n}}$$

$$LSD = t_{0.025, 16-4} \sqrt{\frac{2(12825.7)}{4}}$$

$$LSD = 2.179 \sqrt{6412.85} = 174.495$$

$$\text{Treatment 2 vs. Treatment 4} = 3156.250 - 2666.250 = 490.000 > 174.495$$

$$\text{Treatment 2 vs. Treatment 3} = 3156.250 - 2933.750 = 222.500 > 174.495$$

$$\text{Treatment 2 vs. Treatment 1} = 3156.250 - 2971.000 = 185.250 > 174.495$$

$$\text{Treatment 1 vs. Treatment 4} = 2971.000 - 2666.250 = 304.750 > 174.495$$

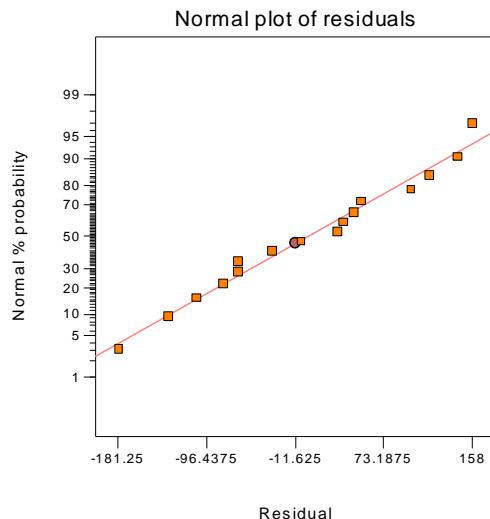

$$\text{Treatment 1 vs. Treatment 3} = 2971.000 - 2933.750 = 37.250 < 174.495$$

$$\text{Treatment 3 vs. Treatment 4} = 2933.750 - 2666.250 = 267.500 > 174.495$$

The Fisher LSD method is also presented in the Design-Expert computer output above. The results agree with the graphical method for this experiment.

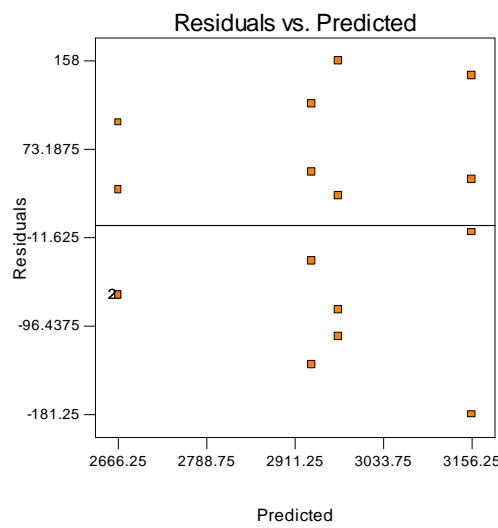

- (d) Construct a normal probability plot of the residuals. What conclusion would you draw about the validity of the normality assumption?

There is nothing unusual about the normal probability plot of residuals.

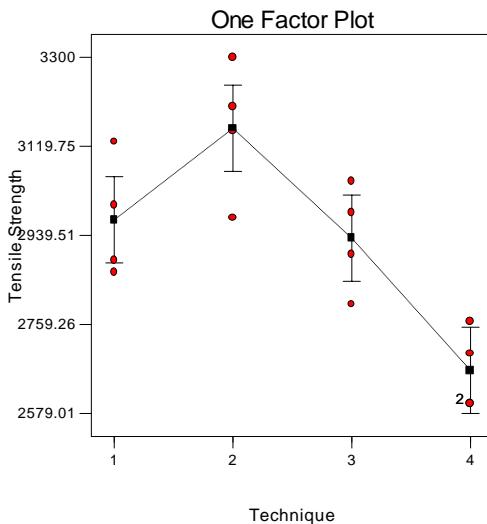

- (e) Plot the residuals versus the predicted tensile strength. Comment on the plot.

There is nothing unusual about this plot.

- (f) Prepare a scatter plot of the results to aid the interpretation of the results of this experiment.

Design-Expert automatically generates the scatter plot. The plot below also shows the sample average for each treatment and the 95 percent confidence interval on the treatment mean.

- 3-2** (a) Rework part (b) of Problem 3-1 using Tukey's test with $\alpha = 0.05$. Do you get the same conclusions from Tukey's test that you did from the graphical procedure and/or the Fisher LSD method?

Minitab Output

Tukey's pairwise comparisons

Family error rate = 0.0500
 Individual error rate = 0.0117
 Critical value = 4.20

Intervals for (column level mean) - (row level mean)

	1	2	3
2	-423	53	
3	-201	-15	275
4	67	252	30
	543	728	505

No, the conclusions are not the same. The mean of Treatment 4 is different than the means of Treatments 1, 2, and 3. However, the mean of Treatment 2 is not different from the means of Treatments 1 and 3 according to the Tukey method, they were found to be different using the graphical method and the Fisher LSD method.

- (b) Explain the difference between the Tukey and Fisher procedures.

Both Tukey and Fisher utilize a single critical value; however, Tukey's is based on the studentized range statistic while Fisher's is based on t distribution.

- 3-3** Reconsider the experiment in Problem 3-1. Find a 95 percent confidence interval on the mean tensile strength of the portland cement produced by each of the four mixing techniques. Also find a 95

percent confidence interval on the difference in means for techniques 1 and 3. Does this aid in interpreting the results of the experiment?

$$\bar{y}_i - t_{\alpha/2, N-a} \sqrt{\frac{MS_E}{n}} \leq \mu_i \leq \bar{y}_i + t_{\alpha/2, N-a} \sqrt{\frac{MS_E}{n}}$$

$$\text{Treatment 1: } 2971 \pm 2.179 \sqrt{\frac{1282837}{4}}$$

$$2971 \pm 123.387$$

$$2847.613 \leq \mu_1 \leq 3094.387$$

$$\text{Treatment 2: } 3156.25 \pm 123.387$$

$$3032.863 \leq \mu_2 \leq 3279.637$$

$$\text{Treatment 3: } 2933.75 \pm 123.387$$

$$2810.363 \leq \mu_3 \leq 3057.137$$

$$\text{Treatment 4: } 2666.25 \pm 123.387$$

$$2542.863 \leq \mu_4 \leq 2789.637$$

$$\text{Treatment 1 - Treatment 3: } \bar{y}_i - \bar{y}_j - t_{\alpha/2, N-a} \sqrt{\frac{2MS_E}{n}} \leq \mu_i - \mu_j \leq \bar{y}_i - \bar{y}_j + t_{\alpha/2, N-a} \sqrt{\frac{2MS_E}{n}}$$

$$2971.00 - 2933.75 \pm 2.179 \sqrt{\frac{2(12825.7)}{4}}$$

$$-137.245 \leq \mu_1 - \mu_3 \leq 211.745$$

3-4 A product developer is investigating the tensile strength of a new synthetic fiber that will be used to make cloth for men's shirts. Strength is usually affected by the percentage of cotton used in the blend of materials for the fiber. The engineer conducts an experiment with five levels of cotton content and replicated the experiment five times. The data are shown in the following table.

Cotton Weight Percentage	Observations				
15	7	7	15	11	9
20	12	17	12	18	18
25	14	19	19	18	18
30	19	25	22	19	23
35	7	10	11	15	11

- (a) Is there evidence to support the claim that cotton content affects the mean tensile strength? Use $\alpha = 0.05$.

Minitab Output

One-way ANOVA: Tensile Strength versus Cotton Percentage

Analysis of Variance for Tensile					
Source	DF	SS	MS	F	P
Cotton	4	475.76	118.94	14.76	0.000
Error	20	161.20	8.06		
Total	24	636.96			

Yes, the F -value is 14.76 with a corresponding P -value of 0.000. The percentage of cotton in the fiber appears to have an affect on the tensile strength.

- (b) Use the Fisher LSD method to make comparisons between the pairs of means. What conclusions can you draw?

Minitab Output

Fisher's pairwise comparisons

Family error rate = 0.264
Individual error rate = 0.0500

Critical value = 2.086

Intervals for (column level mean) - (row level mean)

	15	20	25	30
20	-9.346			
25	-11.546	-5.946		
30	-15.546	-9.946	-7.746	
35	-4.746	0.854	3.054	7.054
	2.746	8.346	10.546	14.546

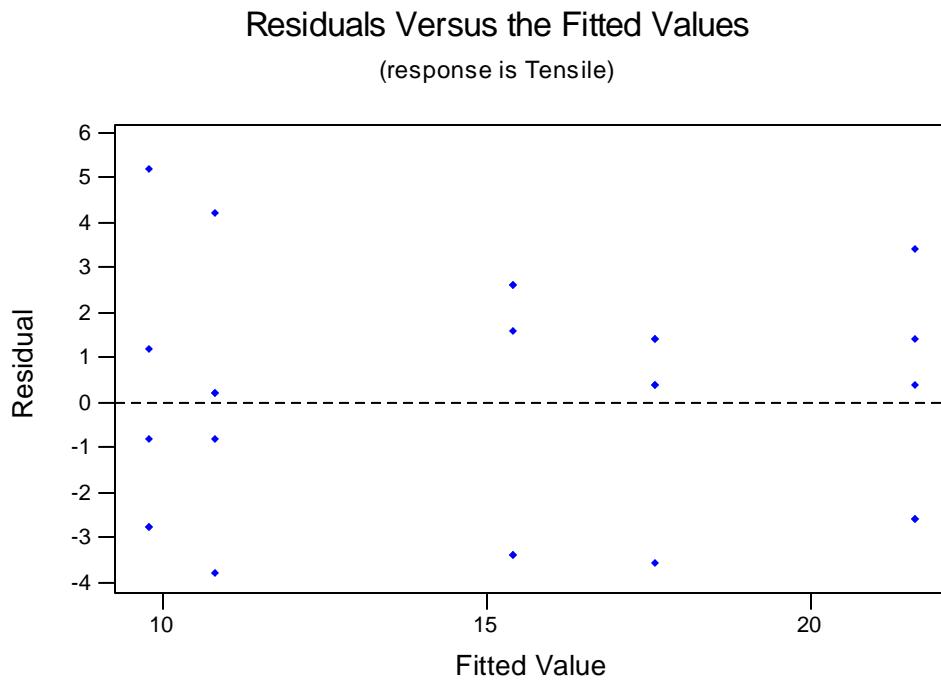

In the Minitab output the pairs of treatments that do not contain zero in the pair of numbers indicates that there is a difference in the pairs of the treatments. 15% cotton is different than 20%, 25% and 30%. 20% cotton is different than 30% and 35% cotton. 25% cotton is different than 30% and 35% cotton. 30% cotton is different than 35%.

- (c) Analyze the residuals from this experiment and comment on model adequacy.

Normal Probability Plot of the Residuals

(response is Tensile)

The residuals show nothing unusual.

3-5 Reconsider the experiment described in Problem 3-4. Suppose that 30 percent cotton content is a control. Use Dunnett's test with $\alpha = 0.05$ to compare all of the other means with the control.

For this problem: $a = 5$, $a-1 = 4$, $f=20$, $n=5$ and $\alpha = 0.05$

$$d_{0.05}(4, 20)\sqrt{\frac{2MS_E}{n}} = 2.65\sqrt{\frac{2(8.06)}{n}} = 4.76$$

$$1 \text{ vs. } 4 : \bar{y}_{1.} - \bar{y}_{4.} = 9.8 - 21.6 = -11.8^*$$

$$2 \text{ vs. } 4 : \bar{y}_{2.} - \bar{y}_{4.} = 15.4 - 21.6 = -6.2^*$$

$$3 \text{ vs. } 4 : \bar{y}_{3.} - \bar{y}_{4.} = 17.6 - 21.6 = -4.0$$

$$5 \text{ vs. } 4 : \bar{y}_{5.} - \bar{y}_{4.} = 10.8 - 21.6 = -10.6^*$$

The control treatment, treatment 4, differs from treatments 1,2 and 5.

3-6 A pharmaceutical manufacturer wants to investigate the bioactivity of a new drug. A completely randomized single-factor experiment was conducted with three dosage levels, and the following results were obtained.

Dosage	Observations			
20g	24	28	37	30
30g	37	44	31	35

40g	42	47	52	38
-----	----	----	----	----

(a) Is there evidence to indicate that dosage level affects bioactivity? Use $\alpha = 0.05$.

Minitab Output

One-way ANOVA: Activity versus Dosage

Analysis of Variance for Activity					
Source	DF	SS	MS	F	P
Dosage	2	450.7	225.3	7.04	0.014
Error	9	288.3	32.0		
Total	11	738.9			

There appears to be a difference in the dosages.

(b) If it is appropriate to do so, make comparisons between the pairs of means. What conclusions can you draw?

Because there appears to be a difference in the dosages, the comparison of means is appropriate.

Minitab Output

Tukey's pairwise comparisons

Family error rate = 0.0500
Individual error rate = 0.0209

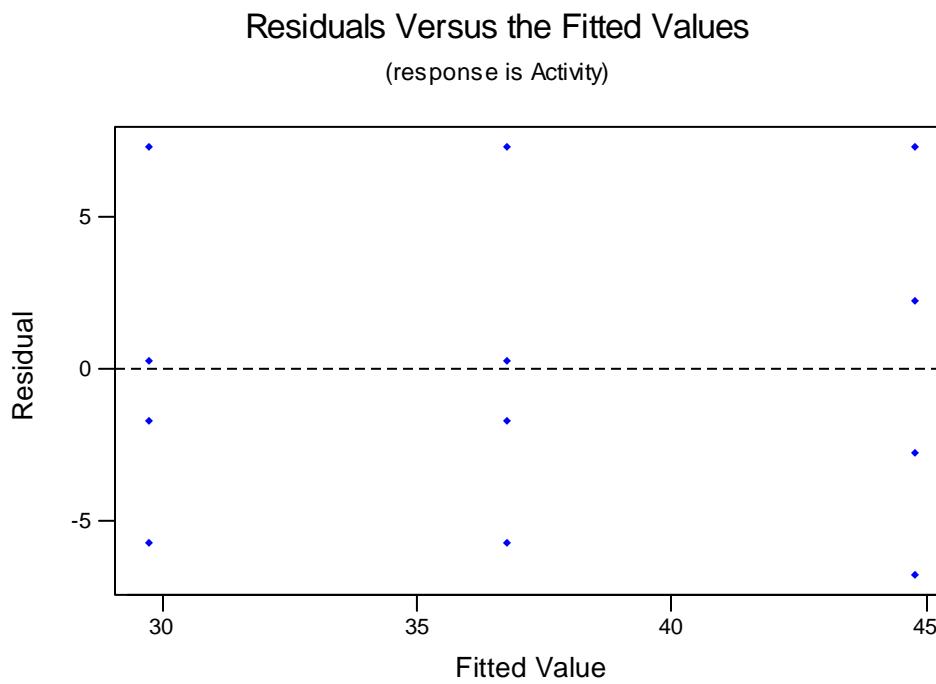

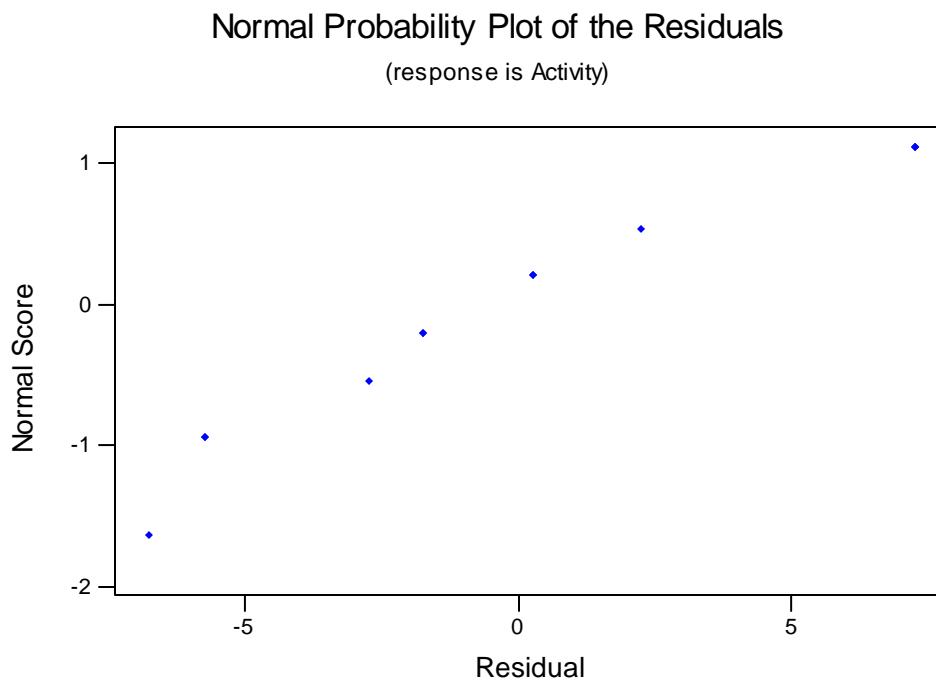

Critical value = 3.95

Intervals for (column level mean) - (row level mean)

	20g	30g
30g	-18.177 4.177	
40g	-26.177 -3.823	-19.177 3.177

The Tukey comparison shows a difference in the means between the 20g and the 40g dosages.

(c) Analyze the residuals from this experiment and comment on the model adequacy.

There is nothing too unusual about the residuals.

3-7 A rental car company wants to investigate whether the type of car rented affects the length of the rental period. An experiment is run for one week at a particular location, and 10 rental contracts are selected at random for each car type. The results are shown in the following table.

Type of Car	Observations									
	3	5	3	7	6	5	3	2	1	6
Sub-compact	3	5	3	7	6	5	3	2	1	6
Compact	1	3	4	7	5	6	3	2	1	7
Midsize	4	1	3	5	7	1	2	4	2	7
Full Size	3	5	7	5	10	3	4	7	2	7

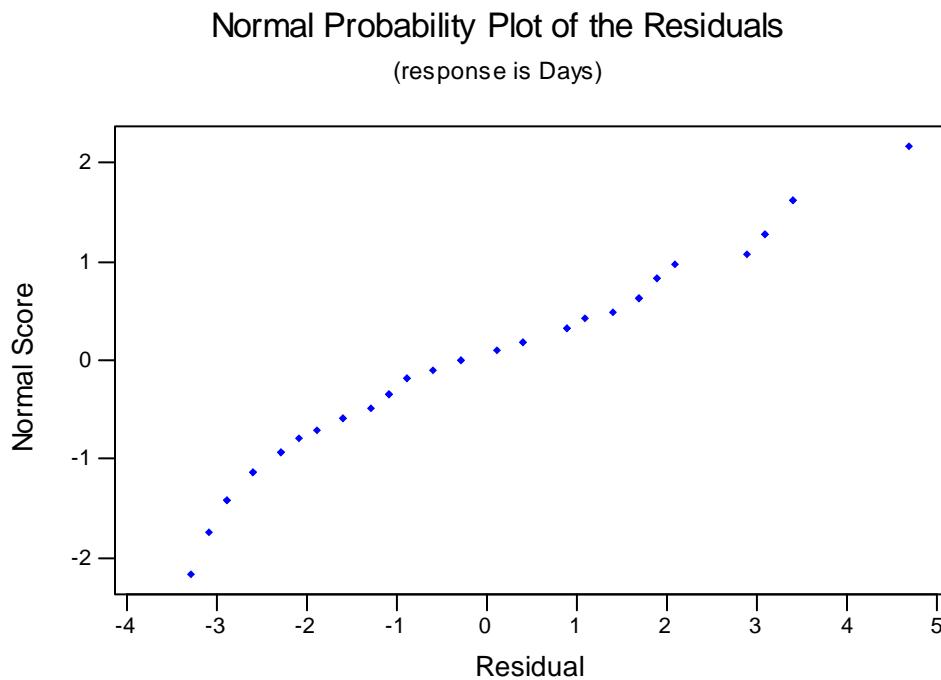

- (a) Is there evidence to support a claim that the type of car rented affects the length of the rental contract? Use $\alpha = 0.05$. If so, which types of cars are responsible for the difference?

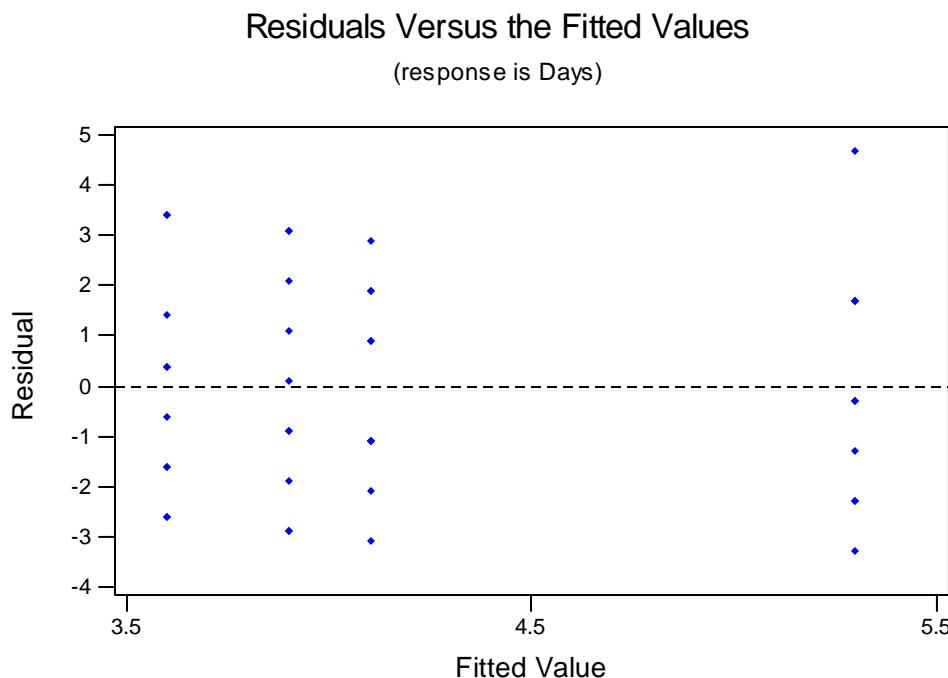

Minitab Output

One-way ANOVA: Days versus Car Type					
Analysis of Variance for Days					
Source	DF	SS	MS	F	P
Car Type	3	16.68	5.56	1.11	0.358
Error	36	180.30	5.01		
Total	39	196.98			

There is no difference.

- (b) Analyze the residuals from this experiment and comment on the model adequacy.

There is nothing unusual about the residuals.

- (c) Notice that the response variable in this experiment is a count. Should the cause any potential concerns about the validity of the analysis of variance?

Because the data is count data, a square root transformation could be applied. The analysis is shown below. It does not change the interpretation of the data.

Minitab Output

One-way ANOVA: Sqrt Days versus Car Type

Analysis of Variance for Sqrt Day					
Source	DF	SS	MS	F	P
Car Type	3	1.087	0.362	1.10	0.360
Error	36	11.807	0.328		
Total	39	12.893			

3-8 I belong to a golf club in my neighborhood. I divide the year into three golf seasons: summer (June-September), winter (November-March) and shoulder (October, April and May). I believe that I play my best golf during the summer (because I have more time and the course isn't crowded) and shoulder (because the course isn't crowded) seasons, and my worst golf during the winter (because all of the part-year residents show up, and the course is crowded, play is slow, and I get frustrated). Data from the last year are shown in the following table.

Season	Observations									
	83	85	85	87	90	88	88	84	91	90
Summer	83	85	85	87	90	88	88	84	91	90
Shoulder	91	87	84	87	85	86	83			
Winter	94	91	87	85	87	91	92	86		

- (a) Do the data indicate that my opinion is correct? Use $\alpha = 0.05$.

Minitab Output

One-way ANOVA: Score versus Season

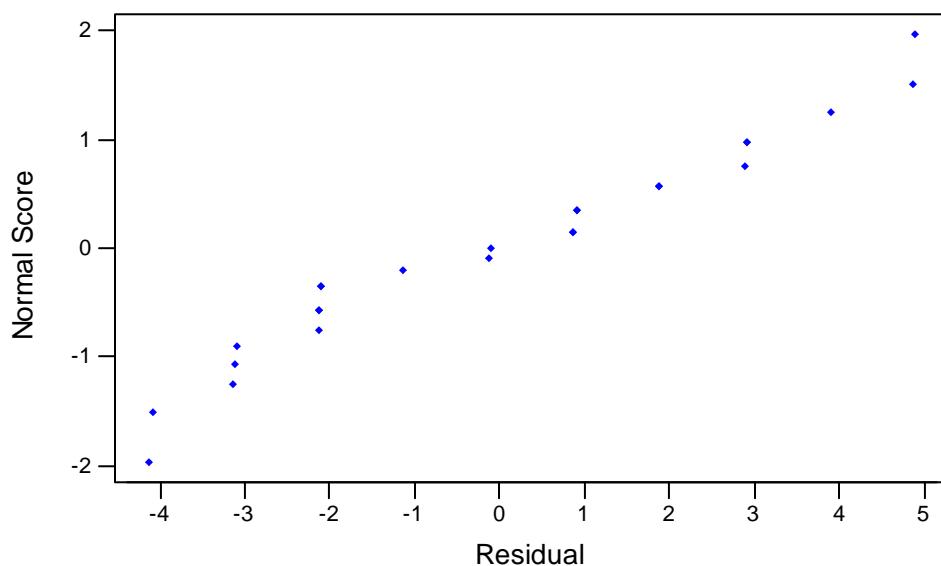

Analysis of Variance for Score					
Source	DF	SS	MS	F	P
Season	2	35.61	17.80	2.12	0.144
Error	22	184.63	8.39		
Total	24	220.24			

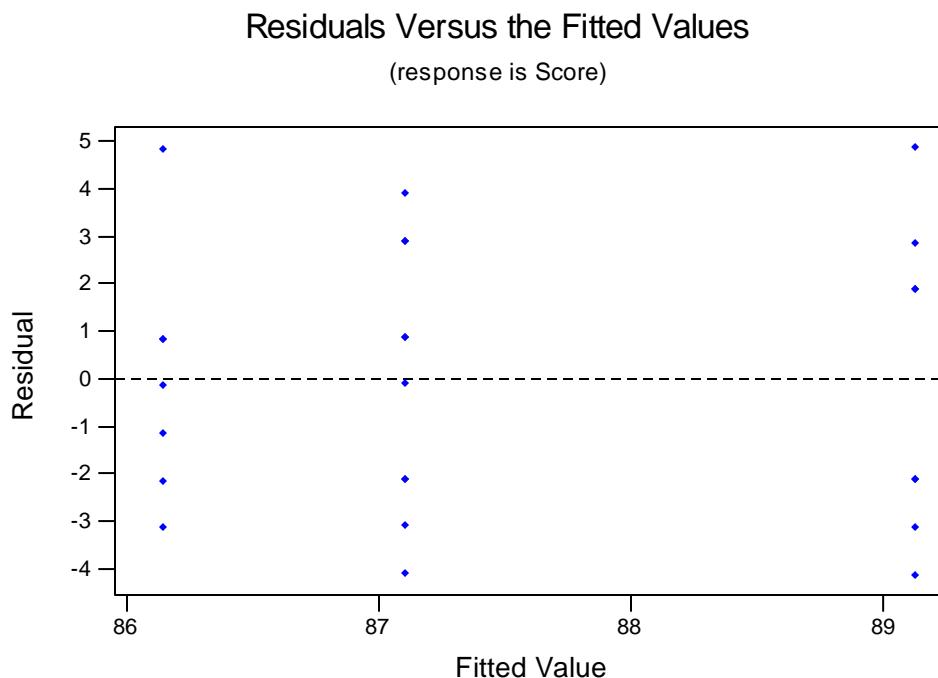

The data do not support the author's opinion.

- (b) Analyze the residuals from this experiment and comment on model adequacy.

Normal Probability Plot of the Residuals

(response is Score)

There is nothing unusual about the residuals.

3-9 A regional opera company has tried three approaches to solicit donations from 24 potential sponsors. The 24 potential sponsors were randomly divided into three groups of eight, and one approach was used for each group. The dollar amounts of the resulting contributions are shown in the following table.

Approach	Contributions (in \$)							
	1	1000	1500	1200	1800	1600	1100	1000
2	1500	1800	2000	1200	2000	1700	1800	1900
3	900	1000	1200	1500	1200	1550	1000	1100

(a) Do the data indicate that there is a difference in results obtained from the three different approaches? Use $\alpha = 0.05$.

Minitab Output

One-way ANOVA: Contribution versus Approach

Source	DF	SS	MS	F	P
Approach	2	1362708	681354	9.41	0.001
Error	21	1520625	72411		
Total	23	2883333			

There is a difference between the approaches. The Tukey test will indicate which are different. Approach 2 is different than approach 3.

Minitab Output

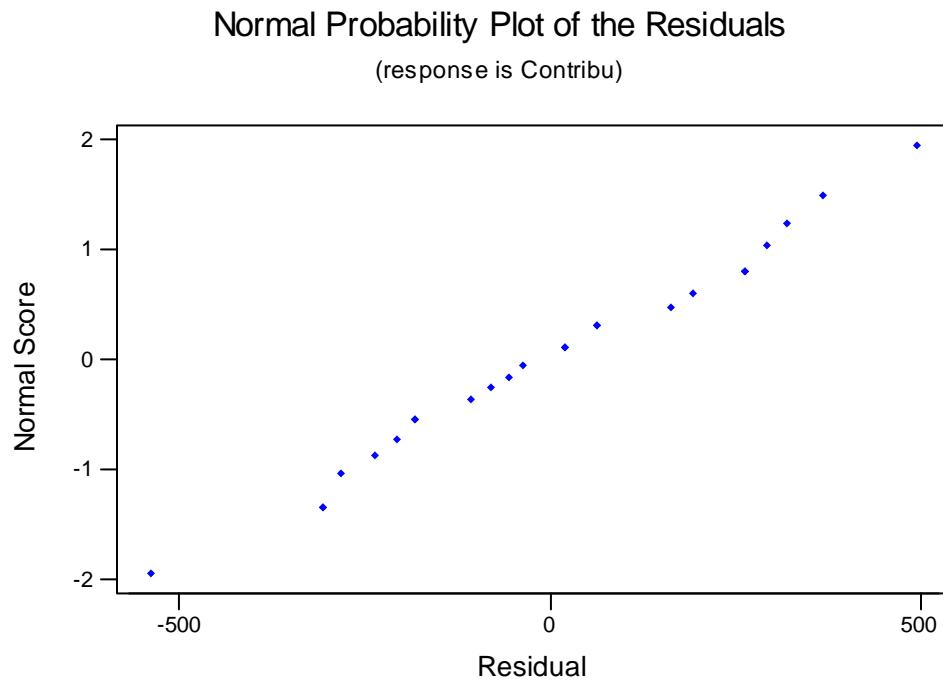

Tukey's pairwise comparisons

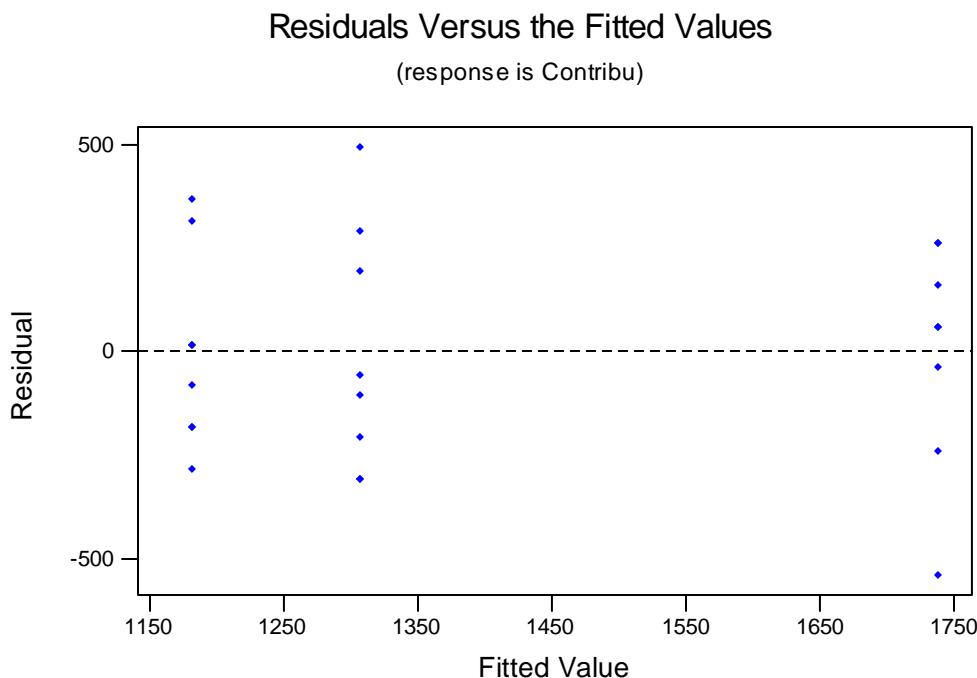

Family error rate = 0.0500
Individual error rate = 0.0200

Critical value = 3.56

Intervals for (column level mean) - (row level mean)		
	1	2
2	-770 -93	
3	-214 464	218 895

(b) Analyze the residuals from this experiment and comment on the model adequacy.

There is nothing unusual about the residuals.

3-10 An experiment was run to determine whether four specific firing temperatures affect the density of a certain type of brick. The experiment led to the following data:

Temperature	Density				
100	21.8	21.9	21.7	21.6	21.7
125	21.7	21.4	21.5	21.4	
150	21.9	21.8	21.8	21.6	21.5
175	21.9	21.7	21.8	21.4	

(a) Does the firing temperature affect the density of the bricks? Use $\alpha = 0.05$.

No, firing temperature does not affect the density of the bricks. Refer to the Design-Expert output below.

Design Expert Output

Response: Density						
ANOVA for Selected Factorial Model						
Analysis of variance table [Partial sum of squares]						
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	0.16	3	0.052	2.02	0.1569	not significant
A	0.16	3	0.052	2.02	0.1569	
Residual	0.36	14	0.026			
Lack of Fit	0.000	0				
Pure Error	0.36	14	0.026			
Cor Total	0.52	17				

The "Model F-value" of 2.02 implies the model is not significant relative to the noise. There is a 15.69 % chance that a "Model F-value" this large could occur due to noise.

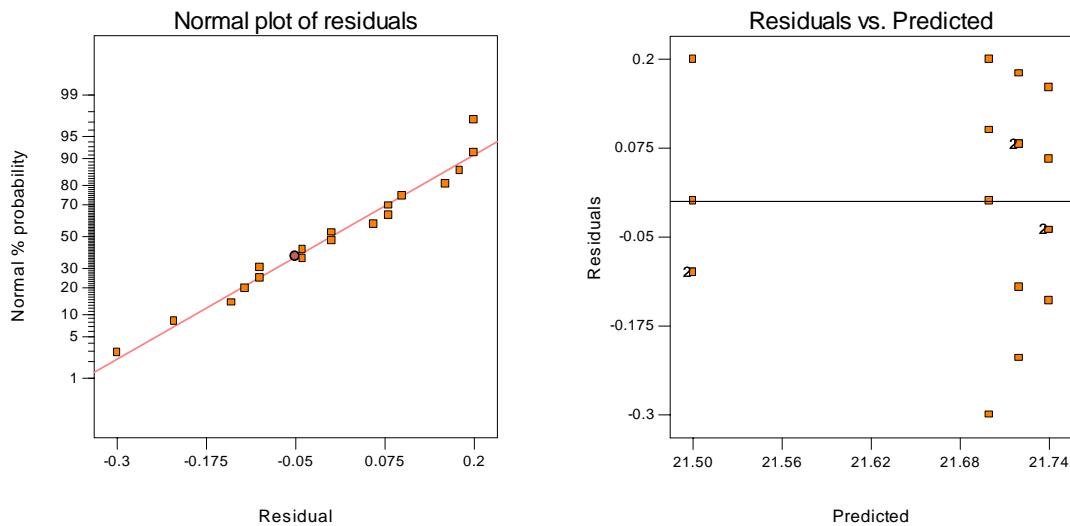

Treatment Means (Adjusted, If Necessary)						
--	--	--	--	--	--	--

Estimated		Standard			
	Mean		Error		
1-100	21.74		0.072		
2-125	21.50		0.080		
3-150	21.72		0.072		
4-175	21.70		0.080		
Treatment	Mean Difference	DF	Standard Error	t for H ₀ Coeff=0	Prob > t
1 vs 2	0.24	1	0.11	2.23	0.0425
1 vs 3	0.020	1	0.10	0.20	0.8465
1 vs 4	0.040	1	0.11	0.37	0.7156
2 vs 3	-0.22	1	0.11	-2.05	0.0601
2 vs 4	-0.20	1	0.11	-1.76	0.0996
3 vs 4	0.020	1	0.11	0.19	0.8552

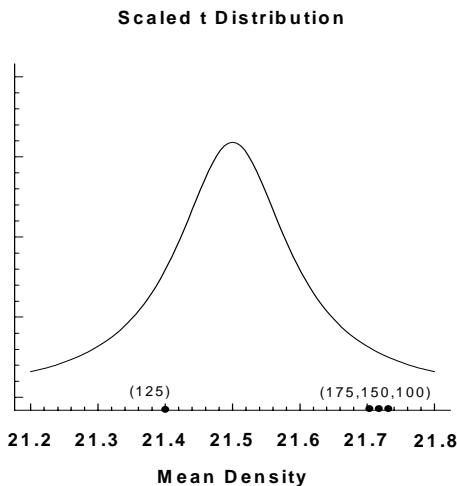

- (b) Is it appropriate to compare the means using the Fisher LSD method in this experiment?

The analysis of variance tells us that there is no difference in the treatments. There is no need to proceed with Fisher's LSD method to decide which mean is different.

- (c) Analyze the residuals from this experiment. Are the analysis of variance assumptions satisfied? There is nothing unusual about the residual plots.

- (d) Construct a graphical display of the treatments as described in Section 3-5.3. Does this graph adequately summarize the results of the analysis of variance in part (b). Yes.

3-11 Rework Part (d) of Problem 3-10 using the Tukey method. What conclusions can you draw? Explain carefully how you modified the procedure to account for unequal sample sizes.

When sample sizes are unequal, the appropriate formula for the Tukey method is

$$T_\alpha = \frac{q_\alpha(a, f)}{\sqrt{2}} \sqrt{MS_E \left(\frac{1}{n_i} + \frac{1}{n_j} \right)}$$

Treatment 1 vs. Treatment 2 = $21.74 - 21.50 = 0.24 < 0.994$

Treatment 1 vs. Treatment 3 = $21.74 - 21.72 = 0.02 < 0.937$

Treatment 1 vs. Treatment 4 = $21.74 - 21.70 = 0.04 < 0.994$

Treatment 3 vs. Treatment 2 = $21.72 - 21.50 = 0.22 < 1.048$

Treatment 4 vs. Treatment 2 = $21.70 - 21.50 = 0.20 < 1.048$

Treatment 3 vs. Treatment 4 = $21.72 - 21.70 = 0.02 < 0.994$

All pairwise comparisons do not identify differences. Notice that there are different critical values for the comparisons depending on the sample sizes of the two groups being compared.

Because we could not reject the hypothesis of equal means using the analysis of variance, we should **never** have performed the Tukey test (or any other multiple comparison procedure, for that matter). If you ignore the analysis of variance results and run multiple comparisons, you will likely make type I errors.

3-12 A manufacturer of television sets is interested in the effect of tube conductivity of four different types of coating for color picture tubes. The following conductivity data are obtained:

Coating Type	Conductivity			
1	143	141	150	146
2	152	149	137	143
3	134	136	132	127
4	129	127	132	129

(a) Is there a difference in conductivity due to coating type? Use $\alpha = 0.05$.

Yes, there is a difference in means. Refer to the Design-Expert output below..

Design Expert Output

1 vs 2	-0.25	1	3.14	-0.080	0.9378
1 vs 3	12.75	1	3.14	4.06	0.0016
1 vs 4	15.75	1	3.14	5.02	0.0003
2 vs 3	13.00	1	3.14	4.14	0.0014
2 vs 4	16.00	1	3.14	5.10	0.0003
3 vs 4	3.00	1	3.14	0.96	0.3578

- (b) Estimate the overall mean and the treatment effects.

$$\hat{\mu} = 2207 / 16 = 137.9375$$

$$\hat{\tau}_1 = \bar{y}_{1\cdot} - \bar{y}_{..} = 145.00 - 137.9375 = 7.0625$$

$$\hat{\tau}_2 = \bar{y}_{2\cdot} - \bar{y}_{..} = 145.25 - 137.9375 = 7.3125$$

$$\hat{\tau}_3 = \bar{y}_{3\cdot} - \bar{y}_{..} = 132.25 - 137.9375 = -5.6875$$

$$\hat{\tau}_4 = \bar{y}_{4\cdot} - \bar{y}_{..} = 129.25 - 137.9375 = -8.6875$$

- (c) Compute a 95 percent interval estimate of the mean of coating type 4. Compute a 99 percent interval estimate of the mean difference between coating types 1 and 4.

$$\text{Treatment 4: } 129.25 \pm 2.179 \sqrt{\frac{19.69}{4}}$$

$$124.4155 \leq \mu_4 \leq 134.0845$$

$$\text{Treatment 1 - Treatment 4: } (145 - 129.25) \pm 3.055 \sqrt{\frac{(2)19.69}{4}}$$

$$6.164 \leq \mu_1 - \mu_4 \leq 25.336$$

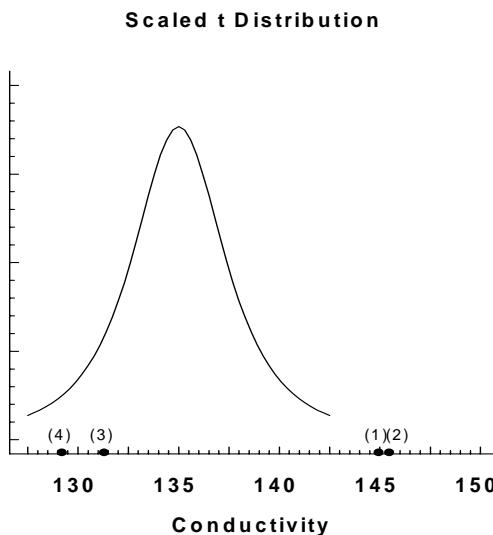

- (d) Test all pairs of means using the Fisher LSD method with $\alpha=0.05$.

Refer to the Design-Expert output above. The Fisher LSD procedure is automatically included in the output.

The means of Coating Type 2 and Coating Type 1 are not different. The means of Coating Type 3 and Coating Type 4 are not different. However, Coating Types 1 and 2 produce higher mean conductivity than does Coating Types 3 and 4.

- (e) Use the graphical method discussed in Section 3-5.3 to compare the means. Which coating produces the highest conductivity?

$$S_{\bar{y}_i} = \sqrt{\frac{MS_E}{n}} = \sqrt{\frac{16.96}{4}} = 2.219 \text{ Coating types 1 and 2 produce the highest conductivity.}$$

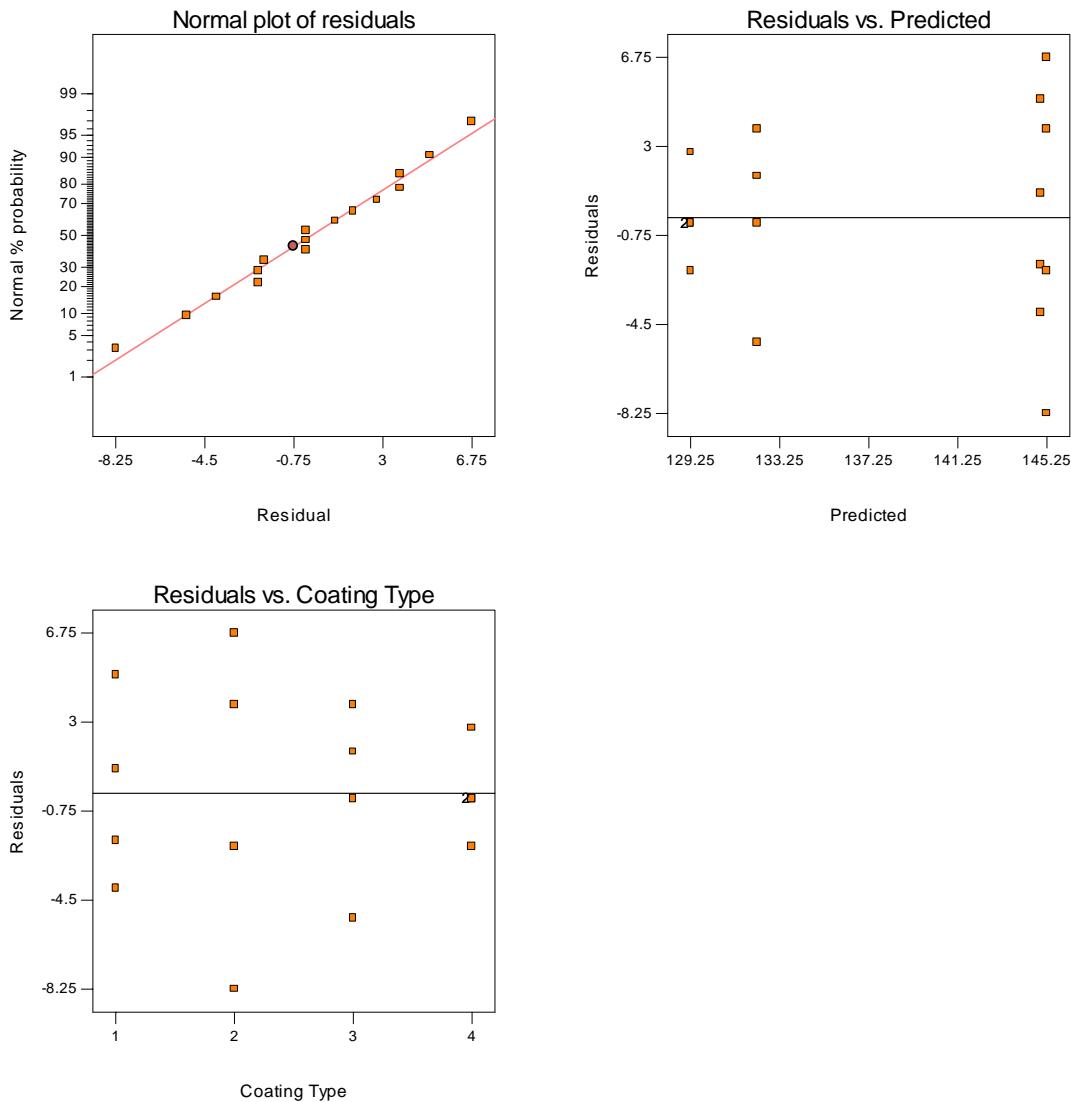

- (f) Assuming that coating type 4 is currently in use, what are your recommendations to the manufacturer?
We wish to minimize conductivity.

Since coatings 3 and 4 do not differ, and as they both produce the lowest mean values of conductivity, use either coating 3 or 4. As type 4 is currently being used, there is probably no need to change.

3-13 Reconsider the experiment in Problem 3-12. Analyze the residuals and draw conclusions about model adequacy.

There is nothing unusual in the normal probability plot. A funnel shape is seen in the plot of residuals versus predicted conductivity indicating a possible non-constant variance.

3-14 An article in the *ACI Materials Journal* (Vol. 84, 1987, pp. 213-216) describes several experiments investigating the rodding of concrete to remove entrapped air. A 3" x 6" cylinder was used, and the number of times this rod was used is the design variable. The resulting compressive strength of the concrete specimen is the response. The data are shown in the following table.

Rodding Level	Compressive Strength		
10	1530	1530	1440
15	1610	1650	1500
20	1560	1730	1530
25	1500	1490	1510

- (a) Is there any difference in compressive strength due to the rodding level? Use $\alpha = 0.05$.

There are no differences.

Design Expert Output

ANOVA for Selected Factorial Model						
Analysis of variance table [Partial sum of squares]						
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	28633.33	3	9544.44	1.87	0.2138	not significant
A	28633.33	3	9544.44	1.87	0.2138	
Residual	40933.33	8	5116.67			
Lack of Fit	0.000	0				
Pure Error	40933.33	8	5116.67			
Cor Total	69566.67	11				

The "Model F-value" of 1.87 implies the model is not significant relative to the noise. There is a 21.38 % chance that a "Model F-value" this large could occur due to noise.

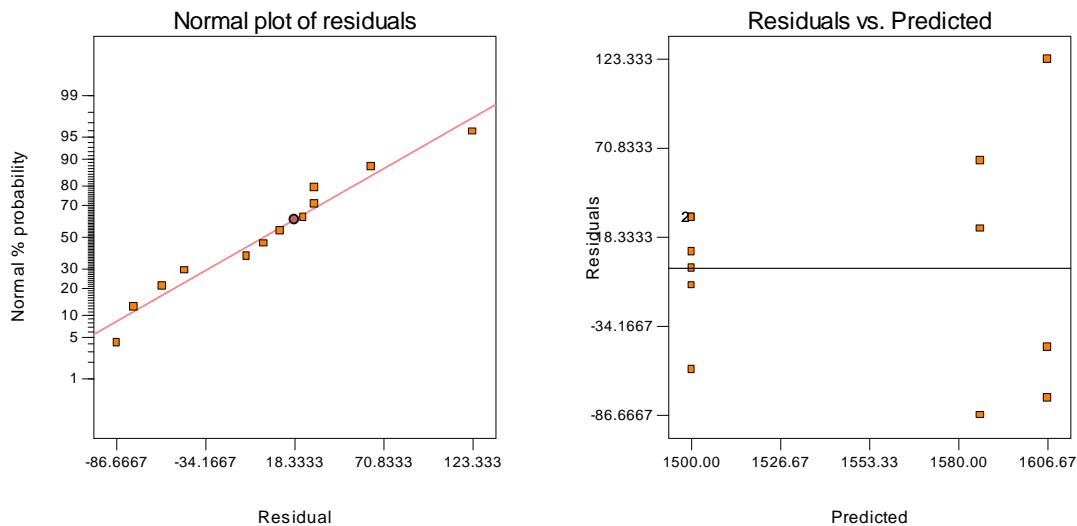

Treatment Means (Adjusted, If Necessary)

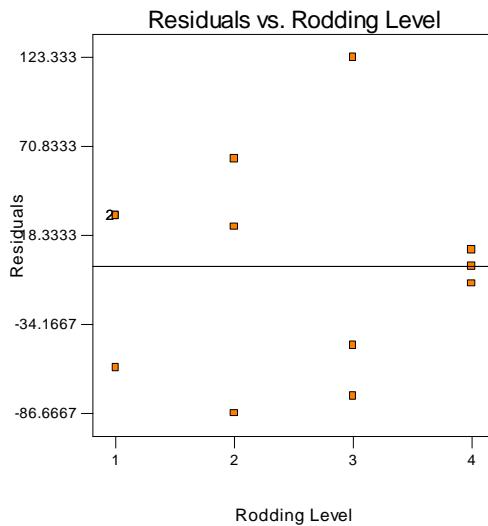

Estimated Standard	
Mean	Error
1-10	1500.00 41.30
2-15	1586.67 41.30
3-20	1606.67 41.30
4-25	1500.00 41.30

Treatment	Mean Difference	Standard DF	t for H ₀ Coeff=0	Prob > t
1 vs 2	-86.67	1 58.40	-1.48	0.1761
1 vs 3	-106.67	1 58.40	-1.83	0.1052
1 vs 4	0.000	1 58.40	0.000	1.0000
2 vs 3	-20.00	1 58.40	-0.34	0.7408
2 vs 4	86.67	1 58.40	1.48	0.1761
3 vs 4	106.67	1 58.40	1.83	0.1052

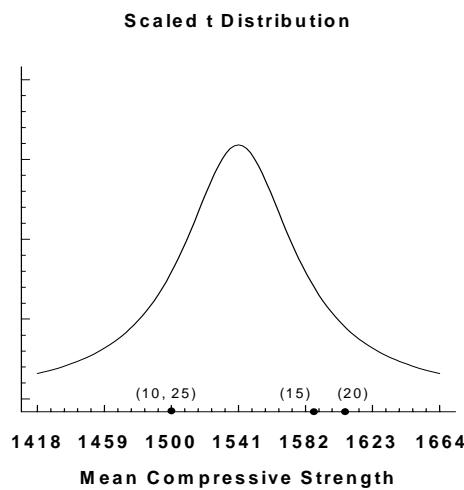

- (b) Find the *P*-value for the *F* statistic in part (a). From computer output, *P*=0.2138.
- (c) Analyze the residuals from this experiment. What conclusions can you draw about the underlying model assumptions?

There is nothing unusual about the residual plots.

- (d) Construct a graphical display to compare the treatment means as describe in Section 3-5.3.

3-15 An article in *Environment International* (Vol. 18, No. 4, 1992) describes an experiment in which the amount of radon released in showers was investigated. Radon enriched water was used in the experiment and six different orifice diameters were tested in shower heads. The data from the experiment are shown in the following table.

Orifice Dia.		Radon Released (%)		
0.37	80	83	83	85
0.51	75	75	79	79
0.71	74	73	76	77
1.02	67	72	74	74
1.40	62	62	67	69
1.99	60	61	64	66

- (a) Does the size of the orifice affect the mean percentage of radon released? Use $\alpha = 0.05$.

Yes. There is at least one treatment mean that is different.

Design Expert Output

Response: Radon Released in %

4 vs 5	6.75	1	1.92	3.52	0.0024
4 vs 6	9.00	1	1.92	4.70	0.0002
5 vs 6	2.25	1	1.92	1.17	0.2557

(b) Find the P-value for the F statistic in part (a). $P=3.161 \times 10^{-8}$

(c) Analyze the residuals from this experiment.

There is nothing unusual about the residuals.

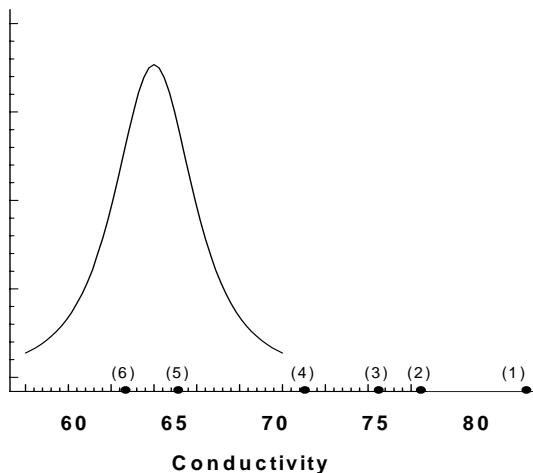

- (d) Find a 95 percent confidence interval on the mean percent radon released when the orifice diameter is 1.40.

$$\text{Treatment 5 (Orifice }=1.40\text{): } 6 \pm 2.101 \sqrt{\frac{7.35}{4}}$$

$$62.152 \leq \mu \leq 67.848$$

- (e) Construct a graphical display to compare the treatment means as described in Section 3-5.3. What conclusions can you draw?

Scaled t Distribution

Treatments 5 and 6 as a group differ from the other means; 2, 3, and 4 as a group differ from the other means, 1 differs from the others.

3-16 The response time in milliseconds was determined for three different types of circuits that could be used in an automatic valve shutoff mechanism. The results are shown in the following table.

Circuit Type	Response Time				
1	9	12	10	8	15
2	20	21	23	17	30
3	6	5	8	16	7

(a) Test the hypothesis that the three circuit types have the same response time. Use $\alpha = 0.01$.

From the computer printout, $F=16.08$, so there is at least one circuit type that is different.

Design Expert Output

Response: Response Time in ms					
ANOVA for Selected Factorial Model					
Analysis of variance table [Partial sum of squares]					
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F
Model	543.60	2	271.80	16.08	0.0004
A	543.60	2	271.80	16.08	0.0004
Residual	202.80	12	16.90		
Lack of Fit	0.000	0			
Pure Error	202.80	12	16.90		
Cor Total	746.40	14			

Treatment Means (Adjusted, If Necessary)					
Treatment	Estimated Mean	Standard Error	t for H0 Coeff=0	Prob > t	
	Mean Difference	DF			
1-1	10.80	1.84			
2-2	22.20	1.84			
3-3	8.40	1.84			

1 vs 2	-11.40	1	2.60	-4.38	0.0009
1 vs 3	2.40	1	2.60	0.92	0.3742
2 vs 3	13.80	1	2.60	5.31	0.0002

- (b) Use Tukey's test to compare pairs of treatment means. Use $\alpha = 0.01$.

$$S_{\bar{y}_i} = \sqrt{\frac{MS_E}{n}} = \sqrt{\frac{1690}{5}} = 1.8385$$

$$q_{0.01, (3,12)} = 5.04$$

$$t_0 = 1.8385(5.04) = 9.266$$

$$1 \text{ vs. } 2: |10.8 - 22.2| = 11.4 > 9.266$$

$$1 \text{ vs. } 3: |10.8 - 8.4| = 2.4 < 9.266$$

$$2 \text{ vs. } 3: |22.2 - 8.4| = 13.8 > 9.266$$

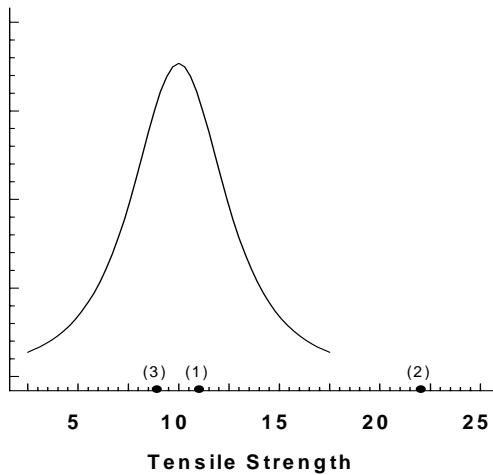

1 and 2 are different. 2 and 3 are different.

Notice that the results indicate that the mean of treatment 2 differs from the means of both treatments 1 and 3, and that the means for treatments 1 and 3 are the same. Notice also that the Fisher LSD procedure (see the computer output) gives the same results.

- (c) Use the graphical procedure in Section 3-5.3 to compare the treatment means. What conclusions can you draw? How do they compare with the conclusions from part (a).

The scaled-*t* plot agrees with part (b). In this case, the large difference between the mean of treatment 2 and the other two treatments is very obvious.

Scaled t Distribution

- (d) Construct a set of orthogonal contrasts, assuming that at the outset of the experiment you suspected the response time of circuit type 2 to be different from the other two.

$$H_0 = \mu_1 - 2\mu_2 + \mu_3 = 0$$

$$H_1 = \mu_1 - 2\mu_2 + \mu_3 \neq 0$$

$$C_1 = y_{1.} - 2y_{2.} + y_{3.}$$

$$C_1 = 54 - 2(111) + 42 = -126$$

$$SS_{C1} = \frac{(-126)^2}{5(6)} = 529.2$$

$$F_{C1} = \frac{529.2}{16.9} = 31.31$$

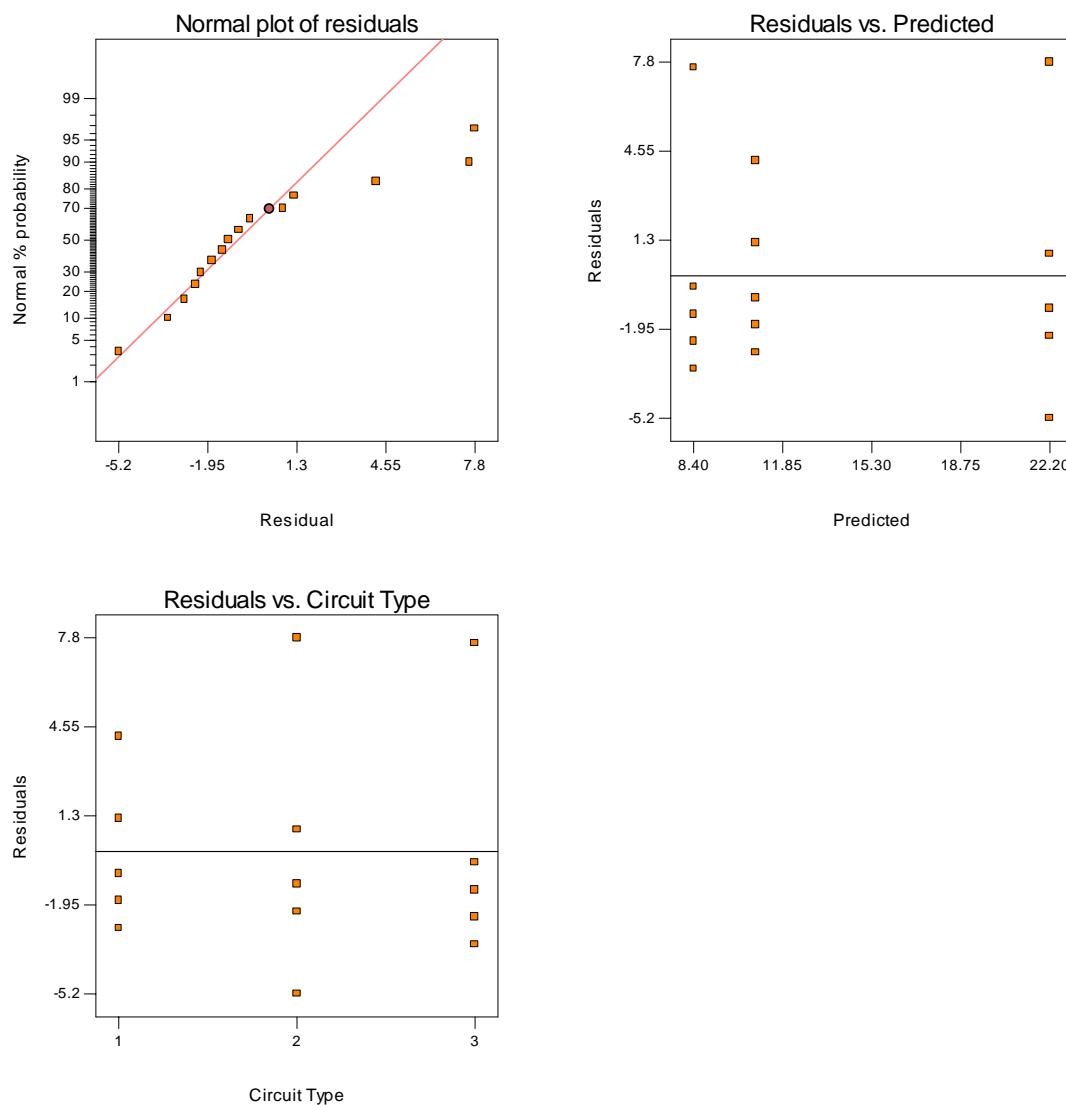

Type 2 differs from the average of type 1 and type 3.

- (e) If you were a design engineer and you wished to minimize the response time, which circuit type would you select?

Either type 1 or type 3 as they are not different from each other and have the lowest response time.

- (f) Analyze the residuals from this experiment. Are the basic analysis of variance assumptions satisfied?

The normal probability plot has some points that do not lie along the line in the upper region. This may indicate potential outliers in the data.

3-17 The effective life of insulating fluids at an accelerated load of 35 kV is being studied. Test data have been obtained for four types of fluids. The results were as follows:

Fluid Type	Life (in h) at 35 kV Load					
1	17.6	18.9	16.3	17.4	20.1	21.6
2	16.9	15.3	18.6	17.1	19.5	20.3
3	21.4	23.6	19.4	18.5	20.5	22.3
4	19.3	21.1	16.9	17.5	18.3	19.8

- (a) Is there any indication that the fluids differ? Use $\alpha = 0.05$.

At $\alpha = 0.05$ there are no difference, but at since the P -value is just slightly above 0.05, there is probably a difference in means.

Design Expert Output

Response: Life in in h					
ANOVA for Selected Factorial Model

Treatment Means (Adjusted, If Necessary)					
Estimated		Standard			
	Mean		Error		
1-1	18.65		0.74		
2-2	17.95		0.74		
3-3	20.95		0.74		
4-4	18.82		0.74		

Treatment	Mean Difference	DF	Standard	t for H0	Prob > t
			Error	Coeff=0	
1 vs 2	0.70	1	1.05	0.67	0.5121
1 vs 3	-2.30	1	1.05	-2.19	0.0403
1 vs 4	-0.17	1	1.05	-0.16	0.8753
2 vs 3	-3.00	1	1.05	-2.86	0.0097
2 vs 4	-0.87	1	1.05	-0.83	0.4183
3 vs 4	2.13	1	1.05	2.03	0.0554

- (b) Which fluid would you select, given that the objective is long life?

Treatment 3. The Fisher LSD procedure in the computer output indicates that the fluid 3 is different from the others, and its average life also exceeds the average lives of the other three fluids.

- (c) Analyze the residuals from this experiment. Are the basic analysis of variance assumptions satisfied?
There is nothing unusual in the residual plots.

3-18 Four different designs for a digital computer circuit are being studied in order to compare the amount of noise present. The following data have been obtained:

Circuit Design			Noise Observed		
1	19	20	19	30	8
2	80	61	73	56	80
3	47	26	25	35	50
4	95	46	83	78	97

(a) Is the amount of noise present the same for all four designs? Use $\alpha = 0.05$.

No, at least one treatment mean is different.

Design Expert Output

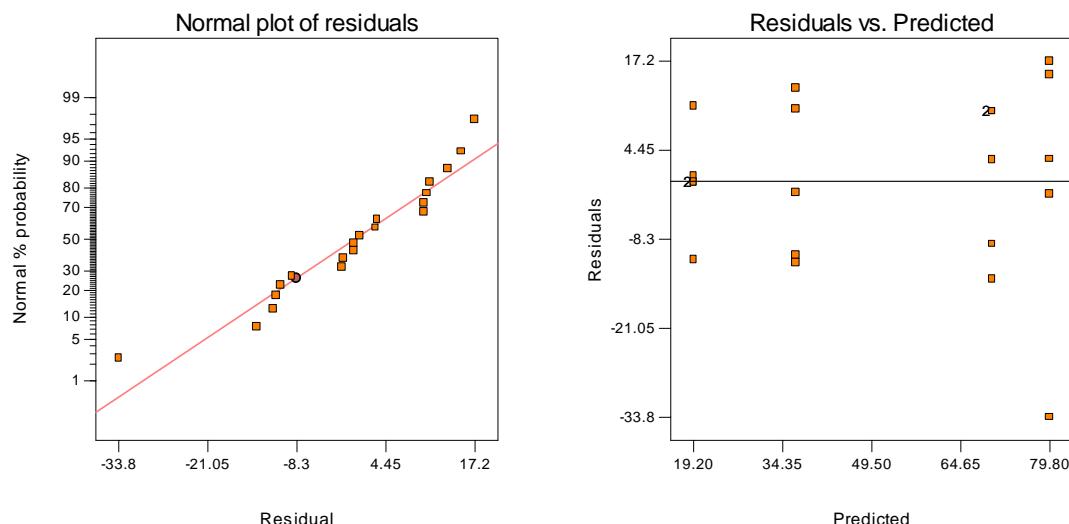

Response: Noise
 ANOVA for Selected Factorial Model
 Analysis of variance table [Partial sum of squares]

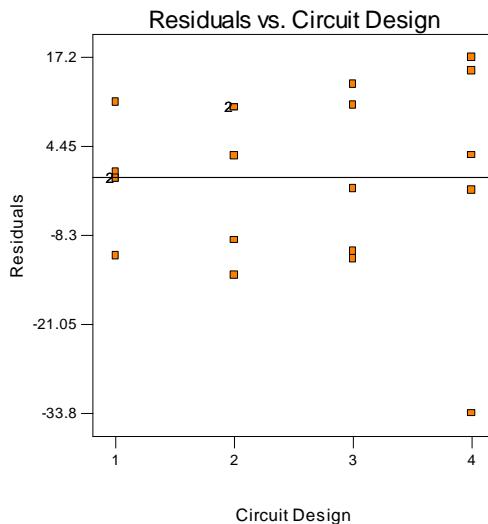

Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	12042.00	3	4014.00	21.78	< 0.0001	
A	12042.00	3	4014.00	21.78	< 0.0001	significant
Residual	2948.80	16	184.30

1-1	19.20		6.07			
2-2	70.00		6.07			
3-3	36.60		6.07			
4-4	79.80		6.07			

Treatment	Mean Difference	DF	Standard Error	t for H ₀	
				Coeff=0	Prob > t
1 vs 2	-50.80	1	8.59	-5.92	< 0.0001
1 vs 3	-17.40	1	8.59	-2.03	0.0597
1 vs 4	-60.60	1	8.59	-7.06	< 0.0001
2 vs 3	33.40	1	8.59	3.89	0.0013
2 vs 4	-9.80	1	8.59	-1.14	0.2705
3 vs 4	-43.20	1	8.59	-5.03	0.0001

- (b) Analyze the residuals from this experiment. Are the basic analysis of variance assumptions satisfied?
There is nothing too unusual about the residual plots, although there is a mild outlier present.

- (c) Which circuit design would you select for use? Low noise is best.

From the Design Expert Output, the Fisher LSD procedure comparing the difference in means identifies Type 1 as having lower noise than Types 2 and 4. Although the LSD procedure comparing Types 1 and 3 has a *P*-value greater than 0.05, it is less than 0.10. Unless there are other reasons for choosing Type 3, Type 1 would be selected.

- 3-19** Four chemists are asked to determine the percentage of methyl alcohol in a certain chemical compound. Each chemist makes three determinations, and the results are the following:

Chemist	Percentage of Methyl Alcohol		
1	84.99	84.04	84.38
2	85.15	85.13	84.88
3	84.72	84.48	85.16
4	84.20	84.10	84.55

- (a) Do chemists differ significantly? Use $\alpha = 0.05$.

There is no significant difference at the 5% level, but chemists differ significantly at the 10% level.

Design Expert Output

Response: Methyl Alcohol in %

3 vs 4	0.50	1	0.27	1.88	0.0966

(b) Analyze the residuals from this experiment.

There is nothing unusual about the residual plots.

- (c) If chemist 2 is a new employee, construct a meaningful set of orthogonal contrasts that might have been useful at the start of the experiment.

Chemists	Total	C1	C2	C3
1	253.41	1	-2	0
2	255.16	-3	0	0
3	254.36	1	1	-1
4	252.85	1	1	1
	Contrast Totals:	-4.86	0.39	-1.51

$$SS_{C1} = \frac{(-4.86)^2}{3(12)} = 0.656 \quad F_{C1} = \frac{0.656}{0.10727} = 6.115^*$$

$$SS_{C2} = \frac{(0.39)^2}{3(6)} = 0.008 \quad F_{C2} = \frac{0.008}{0.10727} = 0.075$$

$$SS_{C3} = \frac{(-1.51)^2}{3(2)} = 0.380 \quad F_{C3} = \frac{0.380}{0.10727} = 3.54$$

Only contrast 1 is significant at 5%.

- 3-20** Three brands of batteries are under study. It is suspected that the lives (in weeks) of the three brands are different. Five batteries of each brand are tested with the following results:

Weeks of Life			
Brand 1	Brand 2	Brand 3	
100	76	108	
96	80	100	
92	75	96	
96	84	98	
92	82	100	

- (a) Are the lives of these brands of batteries different?

Yes, at least one of the brands is different.

Design Expert Output

ANOVA for Selected Factorial Model					
Analysis of variance table [Partial sum of squares]					
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F
Model	1196.13	2	598.07	38.34	< 0.0001

$$79.4 - 100.4 \pm 3.055 \sqrt{\frac{2(15.60)}{5}}$$

$$-28.631 \leq \mu_2 - \mu_3 \leq -13.369$$

- (d) Which brand would you select for use? If the manufacturer will replace without charge any battery that fails in less than 85 weeks, what percentage would the company expect to replace?

Chose brand 3 for longest life. Mean life of this brand in 100.4 weeks, and the variance of life is estimated by 15.60 (MSE). Assuming normality, then the probability of failure before 85 weeks is:

$$\Phi\left(\frac{85-100.4}{\sqrt{15.60}}\right) = \Phi(-3.90) = 0.00005$$

That is, about 5 out of 100,000 batteries will fail before 85 week.

3-21 Four catalysts that may affect the concentration of one component in a three component liquid mixture are being investigated. The following concentrations are obtained:

Catalyst				
1	2	3	4	
58.2	56.3	50.1	52.9	
57.2	54.5	54.2	49.9	
58.4	57.0	55.4	50.0	
55.8	55.3		51.7	
54.9				

- (a) Do the four catalysts have the same effect on concentration?

No, their means are different.

Design Expert Output

Response: Concentration						
ANOVA for Selected Factorial Model						
Analysis of variance table [Partial sum of squares]						
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	85.68	3	28.56	9.92	0.0014	significant

- (b) Plot the residuals versus the predicted response. Construct a normal probability plot of the residuals. What information do these plots convey?

The plot of residuals versus predicted has a strong outward-opening funnel shape, which indicates the variance of the original observations is not constant. The normal probability plot also indicates that the normality assumption is not valid. A data transformation is recommended.

- (c) Based on your answer to part (b) conduct another analysis of the failure time data and draw appropriate conclusions.

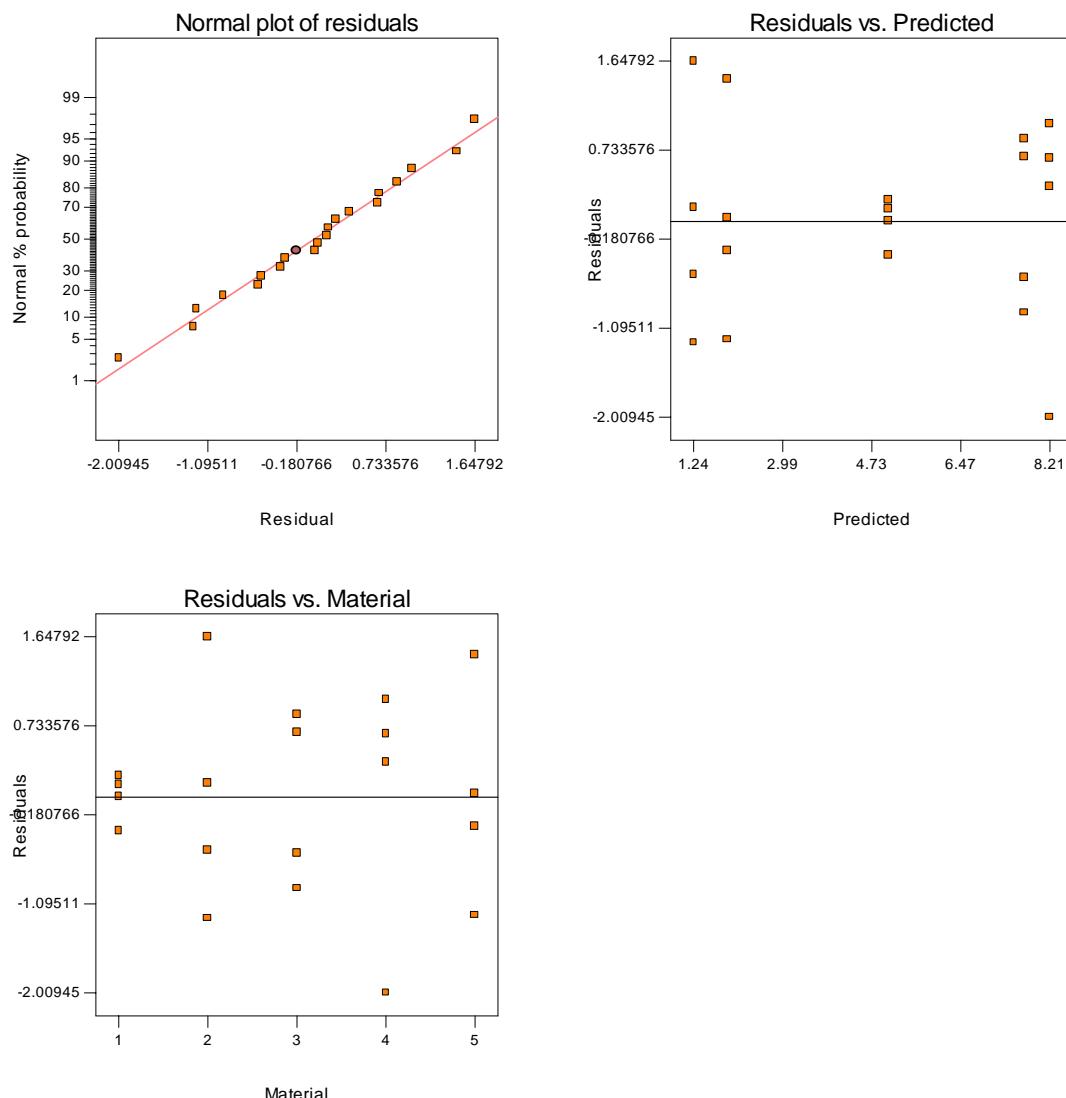

A natural log transformation was applied to the failure time data. The analysis in the log scale identifies that there exists at least one difference in treatment means.

- (b) Plot the residuals versus the predicted response. Construct a normal probability plot of the residuals.
Are there potential concerns about the validity of the assumptions?

The plot of residuals versus predicted appears to be funnel shaped. This indicates the variance of the original observations is not constant. The residuals plotted in the normal probability plot do not fall along a straight line, which suggests that the normality assumption is not valid. A data transformation is recommended.

- (c) Based on your answer to part (b) conduct another analysis of the particle count data and draw appropriate conclusions.

For count data, a square root transformation is often very effective in resolving problems with inequality of variance. The analysis of variance for the transformed response is shown below. The difference between methods is much more apparent after applying the square root transformation.

- 3-24** Consider testing the equality of the means of two normal populations, where the variances are unknown but are assumed to be equal. The appropriate test procedure is the pooled *t* test. Show that the pooled *t* test is equivalent to the single factor analysis of variance.

$$t_0 = \frac{\bar{y}_{1.} - \bar{y}_{2.}}{S_p \sqrt{\frac{2}{n}}} \sim t_{2n-2} \text{ assuming } n_1 = n_2 = n$$

$$S_p = \frac{\sum_{j=1}^n (y_{1j} - \bar{y}_{1.})^2 + \sum_{j=1}^n (y_{2j} - \bar{y}_{2.})^2}{2n-2} = \frac{\sum_{i=1}^2 \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_{1.})^2}{2n-2} \equiv MS_E \text{ for a=2}$$

Furthermore, $(\bar{y}_{1.} - \bar{y}_{2.})^2 \left(\frac{n}{2} \right) = \sum_{i=1}^2 \frac{y_{i.}^2}{n} - \frac{y_{..}^2}{2n}$, which is exactly the same as $SS_{Treatments}$ in a one-way classification with a=2. Thus we have shown that $t_0^2 = \frac{SS_{Treatments}}{MS_E}$. In general, we know that $t_u^2 = F_{1,u}$ so that $t_0^2 \sim F_{1,2n-2}$. Thus the square of the test statistic from the pooled t-test is the same test statistic that results from a single-factor analysis of variance with a=2.

3-25 Show that the variance of the linear combination $\sum_{i=1}^a c_i y_{i.}$ is $\sigma^2 \sum_{i=1}^a n_i c_i^2$.

$$\begin{aligned} V\left[\sum_{i=1}^a c_i y_{i.}\right] &= \sum_{i=1}^a V(c_i y_{i.}) = \sum_{i=1}^a c_i^2 V\left[\sum_{j=1}^{n_i} y_{ij}\right] = \sum_{i=1}^a c_i^2 \sum_{j=1}^{n_i} V(y_{ij.}), V(y_{ij.}) = \sigma^2 \\ &= \sum_{i=1}^a c_i^2 n_i \sigma^2 \end{aligned}$$

3-26 In a fixed effects experiment, suppose that there are n observations for each of four treatments. Let Q_1^2, Q_2^2, Q_3^2 be single-degree-of-freedom components for the orthogonal contrasts. Prove that $SS_{Treatments} = Q_1^2 + Q_2^2 + Q_3^2$.

$$C_1 = 3y_{1.} - y_{2.} - y_{3.} - y_{4.} \quad SS_{C1} = Q_1^2$$

$$C_2 = 2y_{2.} - y_{3.} - y_{4.} \quad SS_{C2} = Q_2^2$$

$$C_3 = y_{3.} - y_{4.} \quad SS_{C3} = Q_3^2$$

$$Q_1^2 = \frac{(3y_{1.} - y_{2.} - y_{3.} - y_{4.})^2}{12n}$$

$$Q_2^2 = \frac{(2y_{2.} - y_{3.} - y_{4.})^2}{6n}$$

$$Q_3^2 = \frac{(y_{3.} - y_{4.})^2}{2n}$$

$$Q_1^2 + Q_2^2 + Q_3^2 = \frac{9 \sum_{i=1}^4 y_{i.}^2 - 6 \left(\sum_{i < j} y_{i.} y_{j.} \right)}{12n} \text{ and since}$$

$$\sum_{i < j} \sum_{y_{i..} y_{j..}} = \frac{1}{2} \left(y_{..}^2 - \sum_{i=1}^4 y_{i..}^2 \right), \text{ we have } Q_1^2 + Q_2^2 + Q_3^2 = \frac{12 \sum_{i=1}^4 y_{i..}^2 - 3 y_{..}^2}{12n} = \sum_{i=1}^4 \frac{y_{i..}^2}{n} - \frac{y_{..}^2}{4n} = SS_{Treatments}$$

for a=4.

3-27 Use Bartlett's test to determine if the assumption of equal variances is satisfied in Problem 3-14. Use $\alpha = 0.05$. Did you reach the same conclusion regarding the equality of variance by examining the residual plots?

$$\chi_0^2 = 2.3026 \frac{q}{c}, \text{ where}$$

$$q = (N-a) \log_{10} S_p^2 - \sum_{i=1}^a (n_i - 1) \log_{10} S_i^2$$

$$c = 1 + \frac{1}{3(a-1)} \left(\sum_{i=1}^a (n_i - 1)^{-1} - (N-a)^{-1} \right)$$

$$S_p^2 = \frac{\sum_{i=1}^a (n_i - 1) S_i^2}{N-a}$$

$$S_1^2 = 11.2 \quad S_p^2 = \frac{(5-1)11.2 + (5-1)14.8 + (5-1)20.8}{15-3}$$

$$S_2^2 = 14.8 \quad S_p^2 = \frac{(5-1)11.2 + (5-1)14.8 + (5-1)20.8}{15-3} = 15.6$$

$$S_3^2 = 20.8 \quad c = 1 + \frac{1}{3(3-1)} \left(\sum_{i=1}^3 (5-1)^{-1} - (15-3)^{-1} \right)$$

$$c = 1 + \frac{1}{3(3-1)} \left(\frac{3}{4} + \frac{1}{12} \right) = 1.1389$$

$$q = (N-a) \log_{10} S_p^2 - \sum_{i=1}^a (n_i - 1) \log_{10} S_i^2$$

$$q = (15-3) \log_{10} 15.6 - 4(\log_{10} 11.2 + \log_{10} 14.8 + \log_{10} 20.8)$$

$$q = 14.3175 - 14.150 = 0.1675$$

$$\chi_0^2 = 2.3026 \frac{q}{c} = 2.3026 \frac{0.1675}{1.1389} = 0.3386 \quad \chi_{0.05,4}^2 = 9.49$$

Cannot reject null hypothesis; conclude that the variance are equal. This agrees with the residual plots in Problem 3-16.

3-28 Use the modified Levene test to determine if the assumption of equal variances is satisfied on Problem 3-20. Use $\alpha = 0.05$. Did you reach the same conclusion regarding the equality of variances by examining the residual plots?

The absolute value of Battery Life – brand median is:

$$|y_{ij} - \tilde{y}_i|$$

	<u>Brand 1</u>	<u>Brand 2</u>	<u>Brand 3</u>
4	4	8	
0	0	0	
4	5	4	
0	4	2	
4	2	0	

The analysis of variance indicates that there is not a difference between the different brands and therefore the assumption of equal variances is satisfied.

Cor Total	80.93	14			

3-29 Refer to Problem 3-16. If we wish to detect a maximum difference in mean response times of 10 milliseconds with a probability of at least 0.90, what sample size should be used? How would you obtain a preliminary estimate of σ^2 ?

$$\Phi^2 = \frac{nD^2}{2a\sigma^2}, \text{ use } MS_E \text{ from Problem 3-10 to estimate } \sigma^2.$$

$$\Phi^2 = \frac{n(10)^2}{2(3)(16.9)} = 0.986n$$

$$\text{Letting } \alpha = 0.05, P(\text{accept}) = 0.1, v_1 = a - 1 = 2$$

Trial and Error yields:

n	v_2	Φ	P(accept)
5	12	2.22	0.17
6	15	2.43	0.09
7	18	2.62	0.04

Choose n ≥ 6, therefore N ≥ 18

Notice that we have used an estimate of the variance obtained from the present experiment. This indicates that we probably didn't use a large enough sample (n was 5 in problem 3-10) to satisfy the criteria specified in this problem. However, the sample size was adequate to detect differences in one of the circuit types.

When we have no prior estimate of variability, sometimes we will generate sample sizes for a range of possible variances to see what effect this has on the size of the experiment. Often a knowledgeable expert will be able to bound the variability in the response, by statements such as "the standard deviation is going to be *at least...*" or "the standard deviation shouldn't be larger than...".

3-30 Refer to Problem 3-20.

- (a) If we wish to detect a maximum difference in mean battery life of 0.5 percent with a probability of at least 0.90, what sample size should be used? Discuss how you would obtain a preliminary estimate of σ^2 for answering this question.

Use the MS_E from Problem 3-14.

$$\Phi^2 = \frac{nD^2}{2a\sigma^2} \quad \varPhi^2 = \frac{n(0.005 \times 91.6667)^2}{2(3)(15.60)} = 0.002244n$$

$$\text{Letting } \alpha = 0.05, P(\text{accept}) = 0.1, v_1 = a - 1 = 2$$

Trial and Error yields:

n	v_2	Φ	$P(\text{accept})$
40	117	1.895	0.18
45	132	2.132	0.10
50	147	2.369	0.05

Choose $n \geq 45$, therefore $N \geq 135$

See the discussion from the previous problem about the estimate of variance.

- (b) If the difference between brands is great enough so that the standard deviation of an observation is increased by 25 percent, what sample size should be used if we wish to detect this with a probability of at least 0.90?

$$v_1 = a - 1 = 2 \quad v_2 = N - a = 15 - 3 = 12 \quad \alpha = 0.05 \quad P(\text{accept}) \leq 0.1$$

$$\lambda = \sqrt{1 + n[(1 + 0.01P)^2 - 1]} = \sqrt{1 + n[(1 + 0.01(25))^2 - 1]} = \sqrt{1 + 0.5625n}$$

Trial and Error yields:

n	v_2	λ	$P(\text{accept})$
40	117	4.84	0.13
45	132	5.13	0.11
50	147	5.40	0.10

Choose $n \geq 50$, therefore $N \geq 150$

- 3-31** Consider the experiment in Problem 3-20. If we wish to construct a 95 percent confidence interval on the difference in two mean battery lives that has an accuracy of ± 2 weeks, how many batteries of each brand must be tested?

$$\alpha = 0.05 \quad MS_E = 15.6$$

$$\text{width} = t_{0.025, N-a} \sqrt{\frac{2MS_E}{n}}$$

Trial and Error yields:

n	v_2	t	width

5	12	2.179	5.44
10	27	2.05	3.62
31	90	1.99	1.996
32	93	1.99	1.96

Choose $n \geq 31$, therefore $N \geq 93$

3-32 Suppose that four normal populations have means of $\mu_1=50$, $\mu_2=60$, $\mu_3=50$, and $\mu_4=60$. How many observations should be taken from each population so that the probability of rejecting the null hypothesis of equal population means is at least 0.90? Assume that $\alpha=0.05$ and that a reasonable estimate of the error variance is $\sigma^2=25$.

$$\mu_i = \mu + \tau_i, i = 1, 2, 3, 4$$

$$\begin{aligned} \mu &= \frac{\sum_{i=1}^4 \mu_i}{4} = \frac{220}{4} = 55 & \Phi^2 &= \frac{n \sum \tau_i^2}{a \sigma^2} = \frac{100n}{4(25)} = n \\ \tau_1 &= -5, \tau_2 = 5, \tau_3 = -5, \tau_4 = 5 & \Phi &= \sqrt{n} \\ \sum_{i=1}^4 \tau_i^2 &= 100 \end{aligned}$$

$v_1 = 3, v_2 = 4(n-1), \alpha = 0.05$, From the O.C. curves we can construct the following:

n	Φ	v_2	β	$1-\beta$
4	2.00	12	0.18	0.82
5	2.24	16	0.08	0.92

Therefore, select $n=5$

3-33 Refer to Problem 3-32.

(a) How would your answer change if a reasonable estimate of the experimental error variance were $\sigma^2=36$?

$$\begin{aligned} \Phi^2 &= \frac{n \sum \tau_i^2}{a \sigma^2} = \frac{100n}{4(36)} = 0.6944n \\ \Phi &= \sqrt{0.6944n} \end{aligned}$$

$v_1 = 3, v_2 = 4(n-1), \alpha = 0.05$, From the O.C. curves we can construct the following:

n	Φ	v_2	β	$1-\beta$
5	1.863	16	0.24	0.76
6	2.041	20	0.15	0.85
7	2.205	24	0.09	0.91

Therefore, select $n=7$

- (b) How would your answer change if a reasonable estimate of the experimental error variance were $\sigma^2 = 49$?

$$\Phi^2 = \frac{n \sum \tau_i^2}{a \sigma^2} = \frac{100n}{4(49)} = 0.5102n$$

$$\Phi = \sqrt{0.5102n}$$

$v_1 = 3, v_2 = 4(n-1), \alpha = 0.05$, From the O.C. curves we can construct the following:

n	Φ	v_2	β	$1-\beta$
7	1.890	24	0.16	0.84
8	2.020	28	0.11	0.89
9	2.142	32	0.09	0.91

Therefore, select n=9

- (c) Can you draw any conclusions about the sensitivity of your answer in the particular situation about how your estimate of σ affects the decision about sample size?

As our estimate of variability increases the sample size must increase to ensure the same power of the test.

- (d) Can you make any recommendations about how we should use this general approach to choosing n in practice?

When we have no prior estimate of variability, sometimes we will generate sample sizes for a range of possible variances to see what effect this has on the size of the experiment. Often a knowledgeable expert will be able to bound the variability in the response, by statements such as “the standard deviation is going to be *at least...*” or “the standard deviation shouldn’t be larger than...”.

- 3-34** Refer to the aluminum smelting experiment described in Section 3-8. Verify that ratio control methods do not affect average cell voltage. Construct a normal probability plot of residuals. Plot the residuals versus the predicted values. Is there an indication that any underlying assumptions are violated?

Design Expert Output

3 vs 4	1.16	1	0.18	6.55	< 0.0001

The following residual plots identify the residuals to be normally distributed, randomly distributed through the range of prediction, and uniformly distributed across the different algorithms. This validates the assumptions for the experiment.

3-36 Four different feed rates were investigated in an experiment on a CNC machine producing a component part used in an aircraft auxiliary power unit. The manufacturing engineer in charge of the experiment knows that a critical part dimension of interest may be affected by the feed rate. However, prior experience has indicated that only dispersion effects are likely to be present. That is, changing the feed rate does not affect the average dimension, but it could affect dimensional variability. The engineer makes five production runs at each feed rate and obtains the standard deviation of the critical dimension (in 10^{-3} mm). The data are shown below. Assume that all runs were made in random order.

Feed Rate (in/min)	Production		Run		
	1	2	3	4	5
10	0.09	0.10	0.13	0.08	0.07
12	0.06	0.09	0.12	0.07	0.12
14	0.11	0.08	0.08	0.05	0.06
16	0.19	0.13	0.15	0.20	0.11

(a) Does feed rate have any effect on the standard deviation of this critical dimension?

Because the residual plots were not acceptable for the non-transformed data, a square root transformation was applied to the standard deviations of the critical dimension. Based on the computer output below, the feed rate has an effect on the standard deviation of the critical dimension.

Design Expert Output

- (b) Use the residuals from this experiment to investigate model adequacy. Are there any problems with experimental validity?

The residual plots are satisfactory.

3-37 Consider the data shown in Problem 3-16.

- (a) Write out the least squares normal equations for this problem, and solve them for $\hat{\mu}$ and $\hat{\tau}_i$, using the usual constraint $\left(\sum_{i=1}^3 \hat{\tau}_i = 0\right)$. Estimate $\tau_1 - \tau_2$.

$$\begin{array}{rccccc} 15\hat{\mu} & +5\hat{\tau}_1 & +5\hat{\tau}_2 & +5\hat{\tau}_3 & =207 \\ 5\hat{\mu} & +5\hat{\tau}_1 & & & =54 \\ 5\hat{\mu} & & +5\hat{\tau}_2 & & =111 \\ 15\hat{\mu} & & & +5\hat{\tau}_3 & =42 \end{array}$$

Imposing $\sum_{i=1}^3 \hat{\tau}_i = 0$, therefore $\hat{\mu} = 13.80$, $\hat{\tau}_1 = -3.00$, $\hat{\tau}_2 = 8.40$, $\hat{\tau}_3 = -5.40$

$$\hat{\tau}_1 - \hat{\tau}_2 = -3.00 - 8.40 = -11.40$$

- (b) Solve the equations in (a) using the constraint $\hat{\tau}_3 = 0$. Are the estimators $\hat{\tau}_i$ and $\hat{\mu}$ the same as you found in (a)? Why? Now estimate $\tau_1 - \tau_2$ and compare your answer with that for (a). What statement can you make about estimating contrasts in the τ_i ?

Imposing the constraint, $\hat{\tau}_3 = 0$ we get the following solution to the normal equations: $\hat{\mu} = 8.40$, $\hat{\tau}_1 = 2.40$, $\hat{\tau}_2 = 13.8$, and $\hat{\tau}_3 = 0$. These estimators are not the same as in part (a). However, $\hat{\tau}_1 - \hat{\tau}_2 = 2.40 - 13.80 = -11.40$, is the same as in part (a). The contrasts are estimable.

- (c) Estimate $\mu + \tau_1$, $2\tau_1 - \tau_2 - \tau_3$ and $\mu + \tau_1 + \tau_2$ using the two solutions to the normal equations. Compare the results obtained in each case.

	Contrast	Estimated from Part (a)	Estimated from Part (b)
1	$\mu + \tau_1$	10.80	10.80
2	$2\tau_1 - \tau_2 - \tau_3$	-9.00	-9.00
3	$\mu + \tau_1 + \tau_2$	19.20	24.60

Contrasts 1 and 2 are estimable, 3 is not estimable.

3-38 Apply the general regression significance test to the experiment in Example 3-1. Show that the procedure yields the same results as the usual analysis of variance.

From Table 3-3:

$$y_{..} = 12355$$

from Example 3-1, we have:

$$\begin{aligned} \hat{\mu} &= 617.75 & \hat{\tau}_1 &= -66.55 & \hat{\tau}_2 &= -30.35 \\ \hat{\tau}_3 &= 7.65 & \hat{\tau}_4 &= 89.25 \end{aligned}$$

$\sum_{i=1}^4 \sum_{j=1}^5 y_{ij}^2 = 7,704,511$, with 20 degrees of freedom.

$$\begin{aligned} R(\mu, \tau) &= \hat{\mu} y_{..} + \sum_{i=1}^5 \hat{\tau} y_{i..} \\ &= (617.75)(12355) + (-66.55)(2756) + (-30.35)(2937) + (7.65)(3127) + (89.25)(3535) \\ &= 7,632,301.25 + 66,870.55 = 7,699,172.80 \\ &\quad \text{with 4 degrees of freedom.} \end{aligned}$$

$$SS_E = \sum_{i=1}^4 \sum_{j=1}^5 y_{ij}^2 - R(\mu, \tau) = 7,704,511 - 7,699,172.80 = 5339.2$$

with 20-4 degrees of freedom.

This is identical to the SS_E found in Example 3-1.

The reduced model:

$$R(\mu) = \hat{\mu} y_{..} = (617.75)(12355) = 7,632,301.25, \text{ with 1 degree of freedom.}$$

$$R(\tau|\mu) = R(\mu, \tau) - R(\mu) = 7,699,172.80 - 7,632,301.25 = 66,870.55, \text{ with } 4-1=3 \text{ degrees of freedom.}$$

Note: $R(\tau|\mu) = SS_{Treatment}$ from Example 3-1.

Finally,

$$F_0 = \frac{\frac{R(\tau|\mu)}{3}}{\frac{SS_E}{16}} = \frac{\frac{66,870.55}{3}}{\frac{5339.2}{16}} = \frac{22290.8}{333.7} = 66.8$$

which is the same as computed in Example 3-1.

3-39 Use the Kruskal-Wallis test for the experiment in Problem 3-17. Are the results comparable to those found by the usual analysis of variance?

From Design Expert Output of Problem 3-17

Response: Life in h ANOVA for Selected Factorial Model						
Analysis of variance table [Partial sum of squares]

Chapter 4

Randomized Blocks, Latin Squares, and Related Designs

Solutions

4-1 A chemist wishes to test the effect of four chemical agents on the strength of a particular type of cloth. Because there might be variability from one bolt to another, the chemist decides to use a randomized block design, with the bolts of cloth considered as blocks. She selects five bolts and applies all four chemicals in random order to each bolt. The resulting tensile strengths follow. Analyze the data from this experiment (use $\alpha = 0.05$) and draw appropriate conclusions.

Chemical	Bolt				
	1	2	3	4	5
1	73	68	74	71	67
2	73	67	75	72	70
3	75	68	78	73	68
4	73	71	75	75	69

2 vs 3	17.25	1	2.08	8.30	0.0002

There is a difference between the means of the three solutions. The Fisher LSD procedure indicates that solution 3 is significantly different than the other two.

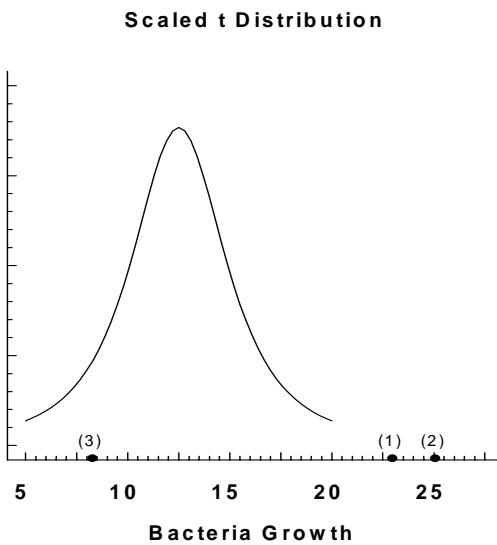

4-3 Plot the mean tensile strengths observed for each chemical type in Problem 4-1 and compare them to a scaled t distribution. What conclusions would you draw from the display?

$$S_{\bar{y}_i} = \sqrt{\frac{MS_E}{b}} = \sqrt{\frac{1.82}{5}} = 0.603$$

There is no obvious difference between the means. This is the same conclusion given by the analysis of variance.

- 4-4** Plot the average bacteria counts for each solution in Problem 4-2 and compare them to an appropriately scaled *t* distribution. What conclusions can you draw?

$$S_{\bar{y}_i} = \sqrt{\frac{MS_E}{b}} = \sqrt{\frac{8.64}{4}} = 1.47$$

There is no difference in mean bacteria growth between solutions 1 and 2. However, solution 3 produces significantly lower mean bacteria growth. This is the same conclusion reached from the Fisher LSD procedure in Problem 4-4.

- 4-5** Consider the hardness testing experiment described in Section 4-1. Suppose that the experiment was conducted as described and the following Rockwell C-scale data (coded by subtracting 40 units) obtained:

Tip	Coupon			
	1	2	3	4
1	9.3	9.4	9.6	10.0
2	9.4	9.3	9.8	9.9
3	9.2	9.4	9.5	9.7
4	9.7	9.6	10.0	10.2

- (a) Analyze the data from this experiment.

There is a difference between the means of the four tips.

Design Expert Output

- (b) Use the Fisher LSD method to make comparisons among the four tips to determine specifically which tips differ in mean hardness readings.

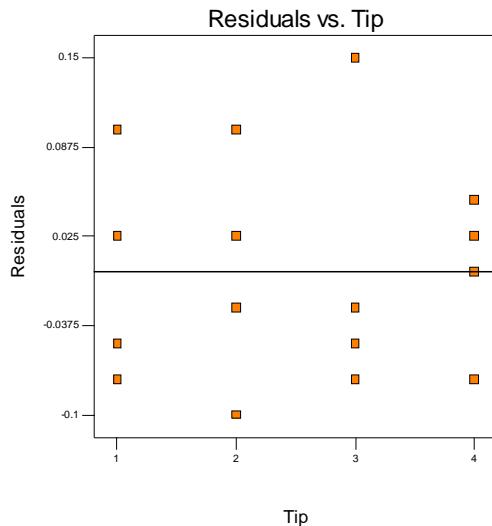

Based on the LSD bars in the Design Expert plot below, the mean of tip 4 differs from the means of tips 1, 2, and 3. The LSD method identifies a marginal difference between the means of tips 2 and 3.

(c) Analyze the residuals from this experiment.

The residual plots below do not identify any violations to the assumptions.

4-6 A consumer products company relies on direct mail marketing pieces as a major component of its advertising campaigns. The company has three different designs for a new brochure and want to evaluate their effectiveness, as there are substantial differences in costs between the three designs. The company decides to test the three designs by mailing 5,000 samples of each to potential customers in four different regions of the country. Since there are known regional differences in the customer base, regions are considered as blocks. The number of responses to each mailing is shown below.

Design	Region			
	NE	NW	SE	SW
1	250	350	219	375
2	400	525	390	580
3	275	340	200	310

(a) Analyze the data from this experiment.

The residuals of the analysis below identify concerns with the normality and equality of variance assumptions. As a result, a square root transformation was applied as shown in the second analysis table. The residuals of both analysis are presented for comparison in part (c) of this problem. The analysis concludes that there is a difference between the mean number of responses for the three designs.

- (b) Use the Fisher LSD method to make comparisons among the three designs to determine specifically which designs differ in mean response rate.

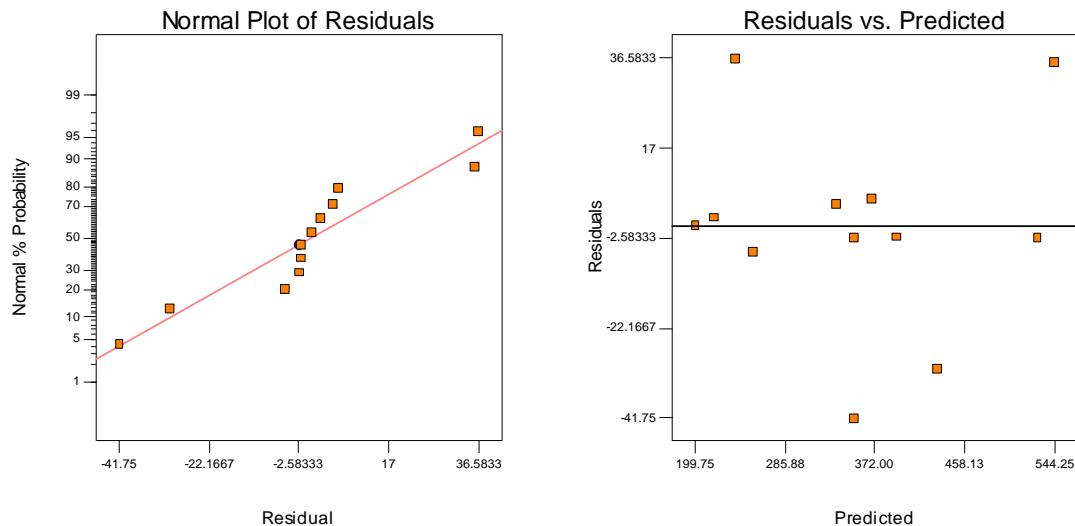

Based on the LSD bars in the Design Expert plot below, designs 1 and 3 do not differ; however, design 2 is different than designs 1 and 3.

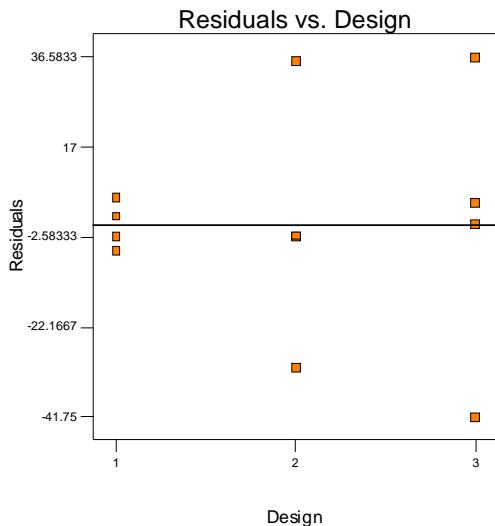

A: Design

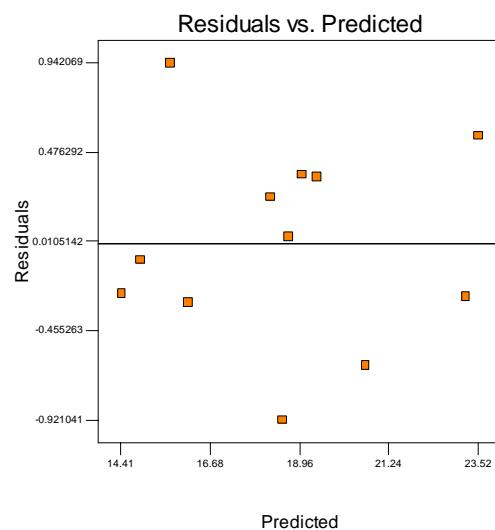

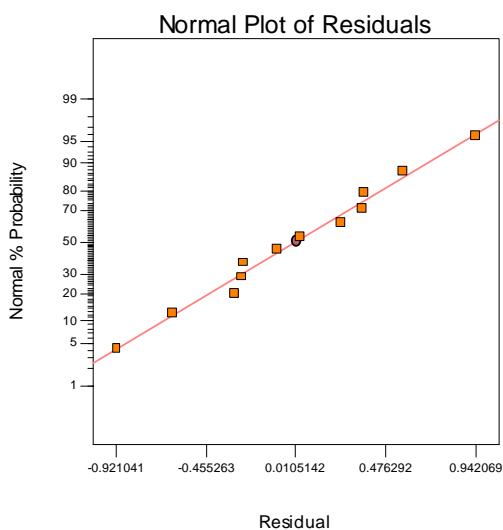

(c) Analyze the residuals from this experiment.

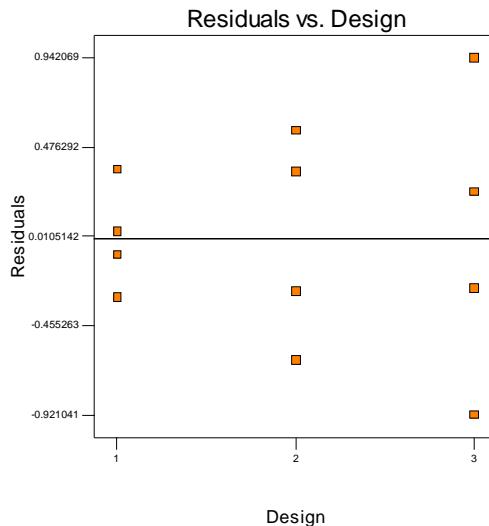

The first set of residual plots presented below represent the untransformed data. Concerns with the normality as well as inequality of variance are presented. The second set of residual plots represent transformed data and do not identify significant violations to the assumptions. The residuals vs. design identify a slight inequality; however, not a strong violation and an improvement to the non-transformed data.

The following are the square root transformed data residual plots.

4-7 The effect of three different lubricating oils on fuel economy is diesel truck engines is being studied. Fuel economy is measured using brake-specific fuel consumption after the engine has been running for 15 minutes. Five different truck engines are available for the study, and the experimenters conduct the following randomized complete block design.

Oil	Truck				
	1	2	3	4	5
1	0.500	0.634	0.487	0.329	0.512

- (b) Use the Fisher LSD method to make comparisons among the three lubricating oils to determine specifically which oils differ in break-specific fuel consumption.

Based on the LSD bars in the Design Expert plot below, the means for break-specific fuel consumption for oils 1 and 3 do not differ; however, oil 2 is different than oils 1 and 3.

- (c) Analyze the residuals from this experiment.

The residual plots below do not identify any violations to the assumptions.

4-8 An article in the *Fire Safety Journal* (“The Effect of Nozzle Design on the Stability and Performance of Turbulent Water Jets,” Vol. 4, August 1981) describes an experiment in which a shape factor was determined for several different nozzle designs at six levels of efflux velocity. Interest focused on potential differences between nozzle designs, with velocity considered as a nuisance variable. The data are shown below:

Nozzle Design	Jet Efflux Velocity (m/s)					
	11.73	14.37	16.59	20.43	23.46	28.74
1	0.78	0.80	0.81	0.75	0.77	0.78
2	0.85	0.85	0.92	0.86	0.81	0.83
3	0.93	0.92	0.95	0.89	0.89	0.83
4	1.14	0.97	0.98	0.88	0.86	0.83
5	0.97	0.86	0.78	0.76	0.76	0.75

- (a) Does nozzle design affect the shape factor? Compare nozzles with a scatter plot and with an analysis of variance, using $\alpha = 0.05$.

A natural log transformation was applied to the pot noise data. The ratio control algorithm does affect the pot noise.

- (c) Conduct any residual analyses that seem appropriate.

The normal probability plot shows slight deviations from normality; however, still acceptable.

- (d) Which ratio control algorithm would you select if your objective is to reduce both the average cell voltage and the pot noise?

Since the ratio control algorithm has little effect on average cell voltage, select the algorithm that minimizes pot noise, that is algorithm #2.

4-10 An aluminum master alloy manufacturer produces grain refiners in ingot form. This company produces the product in four furnaces. Each furnace is known to have its own unique operating characteristics, so any experiment run in the foundry that involves more than one furnace will consider furnace a nuisance variable. The process engineers suspect that stirring rate impacts the grain size of the product. Each furnace can be run at four different stirring rates. A randomized block design is run for a particular refiner and the resulting grain size data is shown below.

Stirring Rate	Furnace			
	1	2	3	4

5	8	4	5	6
10	14	5	6	9
15	14	6	9	2
20	17	9	3	6

(a) Is there any evidence that stirring rate impacts grain size?

3 vs 4	-1.00	1	2.08	-0.48	0.6425

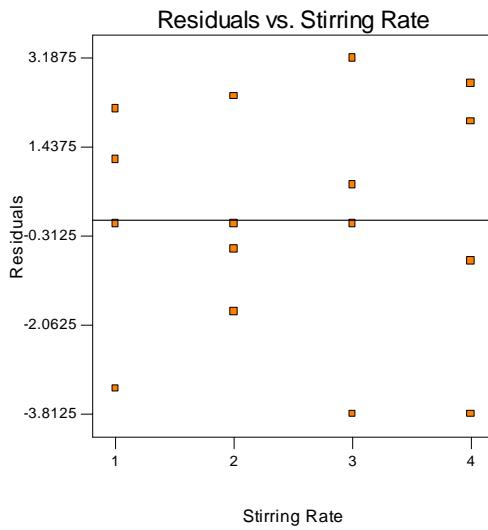

The analysis of variance shown above indicates that there is no difference in mean grain size due to the different stirring rates.

(b) Graph the residuals from this experiment on a normal probability plot. Interpret this plot.

The plot indicates that normality assumption is valid.

- (c) Plot the residuals versus furnace and stirring rate. Does this plot convey any useful information?

The variance is consistent at different stirring rates. Not only does this validate the assumption of uniform variance, it also identifies that the different stirring rates do not affect variance.

- (d) What should the process engineers recommend concerning the choice of stirring rate and furnace for this particular grain refiner if small grain size is desirable?

There really is no effect due to the stirring rate.

4-11 Analyze the data in Problem 4-2 using the general regression significance test.

$$\begin{array}{llllllll}
 \mu : & 12\hat{\mu} & +4\hat{\tau}_1 & +4\hat{\tau}_2 & +4\hat{\tau}_3 & +3\hat{\beta}_1 & +3\hat{\beta}_2 & +3\hat{\beta}_3 & +3\hat{\beta}_4 & =225 \\
 \tau_1 : & 4\hat{\mu} & +4\hat{\tau}_1 & & & +\hat{\beta}_1 & +\hat{\beta}_2 & +\hat{\beta}_3 & +\hat{\beta}_4 & =92 \\
 \tau_2 : & 4\hat{\mu} & & +4\hat{\tau}_2 & & +\hat{\beta}_1 & +\hat{\beta}_2 & +\hat{\beta}_3 & +\hat{\beta}_4 & =101
 \end{array}$$

$$\begin{array}{l}
 \tau_3: \quad 4\hat{\mu} \quad +4\hat{\tau}_3 \quad +\hat{\beta}_1 \quad +\hat{\beta}_2 \quad +\hat{\beta}_3 \quad +\hat{\beta}_4 \quad =32 \\
 \beta_1: \quad 3\hat{\mu} \quad +\hat{\tau}_1 \quad +\hat{\tau}_2 \quad +\hat{\tau}_3 \quad +3\hat{\beta}_1 \quad =34 \\
 \beta_2: \quad 3\hat{\mu} \quad +\hat{\tau}_1 \quad +\hat{\tau}_2 \quad +\hat{\tau}_3 \quad +3\hat{\beta}_2 \quad =50 \\
 \beta_3: \quad 3\hat{\mu} \quad +\hat{\tau}_1 \quad +\hat{\tau}_2 \quad +\hat{\tau}_3 \quad +3\hat{\beta}_3 \quad =36 \\
 \beta_4: \quad 3\hat{\mu} \quad +\hat{\tau}_1 \quad +\hat{\tau}_2 \quad +\hat{\tau}_3 \quad +3\hat{\beta}_4 \quad =105
 \end{array}$$

Applying the constraints $\sum \hat{\tau}_i = \sum \hat{\beta}_j = 0$, we obtain:

$$\begin{aligned}
 \hat{\mu} &= \frac{225}{12}, \quad \hat{\tau}_1 = \frac{51}{12}, \quad \hat{\tau}_2 = \frac{78}{12}, \quad \hat{\tau}_3 = \frac{-129}{12}, \quad \hat{\beta}_1 = \frac{-89}{12}, \quad \hat{\beta}_2 = \frac{-25}{12}, \quad \hat{\beta}_3 = \frac{-81}{12}, \quad \hat{\beta}_4 = \frac{195}{12} \\
 R(\mu, \tau, \beta) &= \left(\frac{225}{12}\right)(225) + \left(\frac{51}{12}\right)(92) + \left(\frac{78}{12}\right)(101) + \left(\frac{-129}{12}\right)(32) + \left(\frac{-89}{12}\right)(34) + \left(\frac{-25}{12}\right)(50) + \\
 &\quad \left(\frac{-81}{12}\right)(36) + \left(\frac{195}{12}\right)(105) = 6029.17
 \end{aligned}$$

$$\sum \sum y_{ij}^2 = 6081, \quad SS_E = \sum \sum y_{ij}^2 - R(\mu, \tau, \beta) = 6081 - 6029.17 = 51.83$$

Model Restricted to $\tau_i = 0$:

$$\begin{array}{l}
 \mu: \quad 12\hat{\mu} \quad +3\hat{\beta}_1 \quad +3\hat{\beta}_2 \quad +3\hat{\beta}_3 \quad +3\hat{\beta}_4 \quad =225 \\
 \beta_1: \quad 3\hat{\mu} \quad +3\hat{\beta}_1 \quad =34 \\
 \beta_2: \quad 3\hat{\mu} \quad +3\hat{\beta}_2 \quad =50 \\
 \beta_3: \quad 3\hat{\mu} \quad +3\hat{\beta}_3 \quad =36 \\
 \beta_4: \quad 3\hat{\mu} \quad +3\hat{\beta}_4 \quad =105
 \end{array}$$

Applying the constraint $\sum \hat{\beta}_j = 0$, we obtain:

$$\begin{aligned}
 \hat{\mu} &= \frac{225}{12}, \quad \hat{\beta}_1 = -89/12, \quad \hat{\beta}_2 = \frac{-25}{12}, \quad \hat{\beta}_3 = \frac{-81}{12}, \quad \hat{\beta}_4 = \frac{195}{12}. \quad \text{Now:} \\
 R(\mu, \beta) &= \left(\frac{225}{12}\right)(225) + \left(\frac{-89}{12}\right)(34) + \left(\frac{-25}{12}\right)(50) + \left(\frac{-81}{12}\right)(36) + \left(\frac{195}{12}\right)(105) = 5325.67 \\
 R(\tau|\mu, \beta) &= R(\mu, \tau, \beta) - R(\mu, \beta) = 6029.17 - 5325.67 = 703.50 = SS_{Treatments}
 \end{aligned}$$

Model Restricted to $\beta_j = 0$:

$$\begin{array}{l}
 \mu: \quad 12\hat{\mu} \quad +4\hat{\tau}_1 \quad +4\hat{\tau}_2 \quad +4\hat{\tau}_3 \quad =225 \\
 \tau_1: \quad 4\hat{\mu} \quad +4\hat{\tau}_1 \quad =92 \\
 \tau_2: \quad 4\hat{\mu} \quad +4\hat{\tau}_2 \quad =101 \\
 \tau_3: \quad 4\hat{\mu} \quad +4\hat{\tau}_3 \quad =32
 \end{array}$$

Applying the constraint $\sum \hat{\tau}_i = 0$, we obtain:

$$\hat{\mu} = \frac{225}{12}, \quad \hat{\tau}_1 = \frac{51}{12}, \quad \hat{\tau}_2 = \frac{78}{12}, \quad \hat{\tau}_3 = \frac{-129}{12}$$

$$R(\mu, \tau) = \left(\frac{225}{12} \right)(225) + \left(\frac{51}{12} \right)(92) + \left(\frac{78}{12} \right)(101) + \left(\frac{-129}{12} \right)(32) = 4922.25$$

$$R(\beta|\mu, \tau) = R(\mu, \tau, \beta) - R(\mu, \tau) = 6029.17 - 4922.25 = 1106.92 = SS_{Blocks}$$

4-12 Assuming that chemical types and bolts are fixed, estimate the model parameters τ_i and β_j in Problem 4-1.

Using Equations 4-14, Applying the constraints, we obtain:

$$\hat{\mu} = \frac{35}{20}, \quad \hat{\tau}_1 = \frac{-23}{20}, \quad \hat{\tau}_2 = \frac{-7}{20}, \quad \hat{\tau}_3 = \frac{13}{20}, \quad \hat{\tau}_4 = \frac{17}{20}, \quad \hat{\beta}_1 = \frac{35}{20}, \quad \hat{\beta}_2 = \frac{-65}{20}, \quad \hat{\beta}_3 = \frac{75}{20}, \quad \hat{\beta}_4 = \frac{20}{20}, \quad \hat{\beta}_5 = \frac{-65}{20}$$

4-13 Draw an operating characteristic curve for the design in Problem 4-2. Does this test seem to be sensitive to small differences in treatment effects?

Assuming that solution type is a fixed factor, we use the OC curve in appendix V. Calculate

$$\phi^2 = \frac{b \sum \tau_i^2}{a \sigma^2} = \frac{4 \sum \tau_i^2}{3(8.69)}$$

using MS_E to estimate σ^2 . We have:

$$v_1 = a - 1 = 2 \quad v_2 = (a - 1)(b - 1) = (2)(3) = 6.$$

If $\sum \hat{\tau}_i^2 = \sigma^2 = MS_E$, then:

$$\phi = \sqrt{\frac{4}{3(1)}} = 1.15 \text{ and } \beta \approx 0.70$$

If $\sum \hat{\tau}_i = 2\sigma^2 = 2MS_E$, then:

$$\phi = \sqrt{\frac{4}{3(2)}} = 1.63 \text{ and } \beta \approx 0.55, \text{ etc.}$$

This test is not very sensitive to small differences.

4-14 Suppose that the observation for chemical type 2 and bolt 3 is missing in Problem 4-1. Analyze the problem by estimating the missing value. Perform the exact analysis and compare the results.

$$y_{23} \text{ is missing. } \hat{y}_{23} = \frac{ay_{2.}^{'} + by_{.3}^{'} - y_{..}^{'}}{(a-1)(b-1)} = \frac{4(282) + 5(227) - 1360}{(4)(3)} = 75.25$$

Thus, $y_{2.} = 357.25$, $y_{.3} = 3022.25$, and $y_{..} = 1435.25$

Source	SS	DF	MS	F ₀

Bolts	158.8875	4	
Error	21.7625	11	1.9784
Total	193.4344	18	

$F_{0.10,3,11}=2.66$, Chemicals are not significant.

4-12 Two missing values in a randomized block. Suppose that in Problem 4-1 the observations for chemical type 2 and bolt 3 and chemical type 4 and bolt 4 are missing.

- (a) Analyze the design by iteratively estimating the missing values as described in Section 4-1.3.

$$\hat{y}_{23} = \frac{4y_2 + 5y_{.3} - y_{..}}{12} \text{ and } \hat{y}_{44} = \frac{4y_4 + 5y_{.4} - y_{..}}{12}$$

Data is coded y-70. As an initial guess, set \hat{y}_{23}^0 equal to the average of the observations available for chemical 2. Thus, $\hat{y}_{23}^0 = \frac{2}{4} = 0.5$. Then,

$$\begin{aligned}\hat{y}_{44}^0 &= \frac{4(8) + 5(6) - 25.5}{12} = 3.04 \\ \hat{y}_{23}^1 &= \frac{4(2) + 5(17) - 28.04}{12} = 5.41 \\ \hat{y}_{44}^1 &= \frac{4(8) + 5(6) - 30.41}{12} = 2.63 \\ \hat{y}_{23}^2 &= \frac{4(2) + 5(17) - 27.63}{12} = 5.44 \\ \hat{y}_{44}^2 &= \frac{4(8) + 5(6) - 30.44}{12} = 2.63 \\ \therefore \hat{y}_{23} &= 5.44 \quad \hat{y}_{44} = 2.63\end{aligned}$$

- (b) Differentiate SS_E with respect to the two missing values, equate the results to zero, and solve for estimates of the missing values. Analyze the design using these two estimates of the missing values.

$$\begin{aligned}SS_E &= \sum \sum y_{ij}^2 - \frac{1}{5} \sum y_{i.}^2 - \frac{1}{4} \sum y_{.j}^2 + \frac{1}{20} \sum y_{..}^2 \\ SS_E &= 0.6 y_{23}^2 + 0.6 y_{44}^2 - 6.8 y_{23} - 3.7 y_{44} + 0.1 y_{23} y_{44} + R\end{aligned}$$

From $\frac{\partial SS_E}{\partial y_{23}} = \frac{\partial SS_E}{\partial y_{44}} = 0$, we obtain:

$$\begin{aligned} 1.2\hat{y}_{23} + 0.1\hat{y}_{44} &= 6.8 \\ 0.1\hat{y}_{23} + 1.2\hat{y}_{44} &= 3.7 \end{aligned} \Rightarrow \hat{y}_{23} = 5.45, \hat{y}_{44} = 2.63$$

These quantities are almost identical to those found in part (a). The analysis of variance using these new data does not differ substantially from part (a).

- (c) Derive general formulas for estimating two missing values when the observations are in *different* blocks.

$$SS_E = y_{iu}^2 + y_{kv}^2 - \frac{(y'_{i.} + y'_{iu})^2 + (y'_{k.} + y_{kv})^2}{b} - \frac{(y'_{.u} + y_{iu})^2 + (y'_{.v} + y_{kv})^2}{a} + \frac{(y'_{..} + y_{iu} + y_{kv})^2}{ab}$$

From $\frac{\partial SS_E}{\partial y_{23}} = \frac{\partial SS_E}{\partial y_{44}} = 0$, we obtain:

$$\begin{aligned} \hat{y}_{iu} \left[\frac{(a-1)(b-1)}{ab} \right] &= \frac{ay'_{i.} + by'_{.j} - y'_{..}}{ab} - \frac{\hat{y}_{kv}}{ab} \\ \hat{y}_{kv} \left[\frac{(a-1)(b-1)}{ab} \right] &= \frac{ay'_{k.} + by'_{.v} - y'_{..}}{ab} - \frac{\hat{y}_{iu}}{ab} \end{aligned}$$

whose simultaneous solution is:

$$\begin{aligned} \hat{y}_{iu} &= \frac{y'_{i.} a \left[1 - (a-1)^2 (b-1)^2 - ab \right] + y'_{.u} b \left[1 - (a-1)^2 (b-1)^2 - ab \right] - y'_{..} \left[1 - ab(a-1)^2 (b-1)^2 \right]}{(a-1)(b-1) \left[1 - (a-1)^2 (b-1)^2 \right]} + \frac{ab \left[ay'_{k.} + by'_{.v} - y'_{..} \right]}{\left[1 - (a-1)^2 (b-1)^2 \right]} \\ \hat{y}_{kv} &= \frac{ay'_{i.} + by'_{.u} - (b-1)(a-1) \left[ay'_{k.} + by'_{.v} - y'_{..} \right]}{\left[1 - (a-1)^2 (b-1)^2 \right]} \end{aligned}$$

- (d) Derive general formulas for estimating two missing values when the observations are in the *same* block. Suppose that two observations y_{ij} and y_{kj} are missing, $i \neq k$ (same block j).

$$SS_E = y_{ij}^2 + y_{kj}^2 - \frac{(y'_{i.} + y_{ij})^2 + (y'_{k.} + y_{kj})^2}{b} - \frac{(y'_{.j} + y_{ij} + y_{kj})^2}{a} + \frac{(y'_{..} + y_{ij} + y_{kj})^2}{ab}$$

From $\frac{\partial SS_E}{\partial y_{23}} = \frac{\partial SS_E}{\partial y_{44}} = 0$, we obtain

$$\begin{aligned} \hat{y}_{ij} &= \frac{ay'_{i.} + by'_{.j} - y'_{..}}{(a-1)(b-1)} + \hat{y}_{kj}(a-1)(b-1)^2 \\ \hat{y}_{kj} &= \frac{ay'_{k.} + by'_{.j} - y'_{..}}{(a-1)(b-1)} + \hat{y}_{ij}(a-1)(b-1)^2 \end{aligned}$$

whose simultaneous solution is:

$$\hat{y}_{ij} = \frac{ay_{i.} + by_{.j} - y_{..}}{(a-1)(b-1)} + \frac{(b-1)\left[ay_{k.} + by_{.j} - y_{..} + (a-1)(b-1)^2(ay_{i.} + by_{.j} - y_{..})\right]}{\left[1 - (a-1)^2(b-1)\right]^2}$$

$$\hat{y}_{kj} = \frac{ay_{k.} + by_{.j} - y_{..} - (b-1)^2(a-1)\left[ay_{i.} + by_{.j} - y_{..}\right]}{(a-1)(b-1)\left[1 - (a-1)^2(b-1)^4\right]}$$

- 4-17** An industrial engineer is conducting an experiment on eye focus time. He is interested in the effect of the distance of the object from the eye on the focus time. Four different distances are of interest. He has five subjects available for the experiment. Because there may be differences among individuals, he decides to conduct the experiment in a randomized block design. The data obtained follow. Analyze the data from this experiment (use $\alpha = 0.05$) and draw appropriate conclusions.

Distance has a statistically significant effect on mean focus time.

4-18 The effect of five different ingredients (*A*, *B*, *C*, *D*, *E*) on reaction time of a chemical process is being studied. Each batch of new material is only large enough to permit five runs to be made. Furthermore, each run requires approximately 1 1/2 hours, so only five runs can be made in one day. The experimenter decides to run the experiment as a Latin square so that day and batch effects can be systematically controlled. She obtains the data that follow. Analyze the data from this experiment (use $\alpha = 0.05$) and draw conclusions.

4-19 An industrial engineer is investigating the effect of four assembly methods (*A*, *B*, *C*, *D*) on the assembly time for a color television component. Four operators are selected for the study. Furthermore, the engineer knows that each assembly method produces such fatigue that the time required for the last assembly may be greater than the time required for the first, regardless of the method. That is, a trend develops in the required assembly time. To account for this source of variability, the engineer uses the Latin square design shown below. Analyze the data from this experiment ($\alpha = 0.05$) draw appropriate conclusions.

4-21 Consider a $p \times p$ Latin square with rows (α_i), columns (β_k), and treatments (τ_j) fixed. Obtain least squares estimates of the model parameters $\alpha_i, \beta_k, \tau_j$.

$$\begin{aligned}\mu &: p^2\hat{\mu} + p\sum_{i=1}^p \hat{\alpha}_i + p\sum_{j=1}^p \hat{\tau}_j + p\sum_{k=1}^p \hat{\beta}_k = y_{...} \\ \alpha_i &: p\hat{\mu} + p\hat{\alpha}_i + p\sum_{j=1}^p \hat{\tau}_j + p\sum_{k=1}^p \hat{\beta}_k = y_{i..}, \quad i=1,2,\dots,p \\ \tau_j &: p\hat{\mu} + p\sum_{i=1}^p \hat{\alpha}_i + p\hat{\tau}_j + p\sum_{k=1}^p \hat{\beta}_k = y_{.j.}, \quad j=1,2,\dots,p \\ \beta_k &: p\hat{\mu} + p\sum_{i=1}^p \hat{\alpha}_i + p\sum_{j=1}^p \hat{\tau}_j + p\hat{\beta}_k = y_{..k}, \quad k=1,2,\dots,p\end{aligned}$$

There are $3p+1$ equations in $3p+1$ unknowns. The rank of the system is $3p-2$. Three side conditions are

necessary. The usual conditions imposed are: $\sum_{i=1}^p \hat{\alpha}_i = \sum_{j=1}^p \hat{\tau}_j = \sum_{k=1}^p \hat{\beta}_k = 0$. The solution is then:

$$\begin{aligned}\hat{\mu} &= \frac{y_{...}}{p^2} = \bar{y}_{...} \\ \hat{\alpha}_i &= \bar{y}_{i..} - \bar{y}_{...}, \quad i=1,2,\dots,p\end{aligned}$$

$$\begin{aligned}\hat{\tau}_j &= \bar{y}_{j\cdot} - \bar{y}_{\dots}, j = 1, 2, \dots, p \\ \hat{\beta}_k &= \bar{y}_{i..} - \bar{y}_{\dots}, k = 1, 2, \dots, p\end{aligned}$$

4-22 Derive the missing value formula (Equation 4-24) for the Latin square design.

$$SS_E = \sum \sum \sum y_{ijk}^2 - \sum \frac{y_{i..}^2}{p} - \sum \frac{y_{.j.}^2}{p} - \sum \frac{y_{..k}^2}{p} + 2 \left(\frac{y_{\dots}^2}{p^2} \right)$$

Let y_{ijk} be missing. Then

$$SS_E = y_{ijk}^2 - \frac{(y'_{i..} + y_{ijk})^2}{p} - \frac{(y'_{.j.} + y_{ijk})^2}{p} - \frac{(y'_{..k} + y_{ijk})^2}{p} + \frac{2(y'_{\dots} + y_{ijk})}{p^2} + R$$

where R is all terms without y_{ijk} . From $\frac{\partial SS_E}{\partial y_{ijk}} = 0$, we obtain:

$$y_{ijk} \frac{(p-1)(p-2)}{p^2} = \frac{p(y'_{i..} + y'_{.j.} + y'_{..k}) - 2y'_{\dots}}{p^2}, \text{ or } y_{ijk} = \frac{p(y'_{i..} + y'_{.j.} + y'_{..k}) - 2y'_{\dots}}{(p-1)(p-2)}$$

4-23 Designs involving several Latin squares. [See Cochran and Cox (1957), John (1971).] The $p \times p$ Latin square contains only p observations for each treatment. To obtain more replications the experimenter may use several squares, say n . It is immaterial whether the squares used are the same or different. The appropriate model is

$$y_{ijkh} = \mu + \rho_h + \alpha_{i(h)} + \tau_j + \beta_{k(h)} + (\tau\rho)_{jh} + \varepsilon_{ijkh} \quad \begin{cases} i = 1, 2, \dots, p \\ j = 1, 2, \dots, p \\ k = 1, 2, \dots, p \\ h = 1, 2, \dots, n \end{cases}$$

where y_{ijkh} is the observation on treatment j in row i and column k of the h th square. Note that $\alpha_{i(h)}$ and $\beta_{k(h)}$ are row and column effects in the h th square, and ρ_h is the effect of the h th square, and $(\tau\rho)_{jh}$ is the interaction between treatments and squares.

- (a) Set up the normal equations for this model, and solve for estimates of the model parameters. Assume that appropriate side conditions on the parameters are $\sum_h \hat{\rho}_h = 0$, $\sum_i \hat{\alpha}_{i(h)} = 0$, and $\sum_k \hat{\beta}_{k(h)} = 0$ for each h , $\sum_j \hat{\tau}_j = 0$, $\sum_j (\hat{\tau}\rho)_{jh} = 0$ for each h , and $\sum_h (\hat{\tau}\rho)_{jh} = 0$ for each j .

$$\begin{aligned}
\hat{\mu} &= \bar{y}_{...} \\
\hat{\rho}_h &= \bar{y}_{...h} - \bar{y}_{...} \\
\hat{\tau}_j &= \bar{y}_{.j..} - \bar{y}_{...} \\
\hat{\alpha}_{i(h)} &= \bar{y}_{i..h} - \bar{y}_{...h} \\
\hat{\beta}_{k(h)} &= \bar{y}_{..kh} - \bar{y}_{...h} \\
\left(\hat{\tau}_{jh} \right) &= \bar{y}_{.j.h} - \bar{y}_{.j..} - \bar{y}_{...h} + \bar{y}_{...}
\end{aligned}$$

(b) Write down the analysis of variance table for this design.

4-24 Discuss how the operating characteristics curves in the Appendix may be used with the Latin square design.

For the fixed effects model use:

$$\Phi^2 = \frac{\sum p \tau_j^2}{p \sigma^2} = \sum \frac{\tau_j^2}{\sigma^2}, \quad v_1 = p-1 \quad v_2 = (p-2)(p-1)$$

For the random effects model use:

$$\lambda = \sqrt{1 + \frac{p \sigma_\tau^2}{\sigma^2}}, \quad v_1 = p-1 \quad v_2 = (p-2)(p-1)$$

4-25 Suppose that in Problem 4-14 the data taken on day 5 were incorrectly analyzed and had to be discarded. Develop an appropriate analysis for the remaining data.

Two methods of analysis exist: (1) Use the general regression significance test, or (2) recognize that the design is a Youden square. The data can be analyzed as a balanced incomplete block design with $a = b = 5$, $r = k = 4$ and $\lambda = 3$. Using either approach will yield the same analysis of variance.

Minitab Output

4-30 Consider the randomized block design with one missing value in Problem 4-15. Analyze this data by using the exact analysis of the missing value problem discussed in Section 4-1.4. Compare your results to the approximate analysis of these data given in Table 4-15.

$$\begin{array}{llllllllll}
\mu: & 15\hat{\mu} & +4\hat{\tau}_1 & +3\hat{\tau}_2 & +4\hat{\tau}_3 & +4\hat{\tau}_4 & +4\hat{\beta}_1 & +4\hat{\beta}_2 & +3\hat{\beta}_3 & +4\hat{\beta}_4 & =17 \\
\tau_1: & 4\hat{\mu} & +4\hat{\tau}_1 & & & & +\hat{\beta}_1 & +\hat{\beta}_2 & +\hat{\beta}_3 & +\hat{\beta}_4 & =3 \\
\tau_2: & 3\hat{\mu} & & +3\hat{\tau}_2 & & & +\hat{\beta}_1 & +\hat{\beta}_2 & & +\hat{\beta}_4 & =1 \\
\tau_3: & 4\hat{\mu} & & & +4\hat{\tau}_3 & & +\hat{\beta}_1 & +\hat{\beta}_2 & +\hat{\beta}_3 & +\hat{\beta}_4 & =-2 \\
\tau_4: & 4\hat{\mu} & & & & +4\hat{\tau}_4 & +\hat{\beta}_1 & +\hat{\beta}_2 & +\hat{\beta}_3 & +\hat{\beta}_4 & =15 \\
\beta_1: & 4\hat{\mu} & +\hat{\tau}_1 & +\hat{\tau}_2 & +\hat{\tau}_3 & +\hat{\tau}_4 & +4\hat{\beta}_1 & & & & =-4 \\
\beta_2: & 4\hat{\mu} & +\hat{\tau}_1 & +\hat{\tau}_2 & +\hat{\tau}_3 & +\hat{\tau}_4 & & +3\hat{\beta}_2 & & & =-3 \\
\beta_3: & 3\hat{\mu} & +\hat{\tau}_1 & & +\hat{\tau}_3 & +\hat{\tau}_4 & & & +4\hat{\beta}_3 & & =6 \\
\beta_4: & 4\hat{\mu} & +\hat{\tau}_1 & +\hat{\tau}_2 & +\hat{\tau}_3 & +\hat{\tau}_4 & & & & +4\hat{\beta}_4 & =19
\end{array}$$

Applying the constraints $\sum \hat{\tau}_i = \sum \hat{\beta}_j = 0$, we obtain:

$$\hat{\mu} = \frac{41}{36}, \hat{\tau}_1 = \frac{-14}{36}, \hat{\tau}_2 = \frac{-24}{36}, \hat{\tau}_3 = \frac{-59}{36}, \hat{\tau}_4 = \frac{94}{36}, \hat{\beta}_1 = \frac{-77}{36}, \hat{\beta}_2 = \frac{-68}{36}, \hat{\beta}_3 = \frac{24}{36}, \hat{\beta}_4 = \frac{121}{36}$$

$$R(\mu, \tau, \beta) = \hat{\mu}y_{..} + \sum_{i=1}^4 \hat{\tau}_i y_{i..} + \sum_{j=1}^4 \hat{\beta}_j y_{.j} = 138.78$$

With 7 degrees of freedom.

$$\sum \sum y_{ij}^2 = 145.00, \quad SS_E = \sum \sum y_{ij}^2 - R(\mu, \tau, \beta) = 145.00 - 138.78 = 6.22$$

which is identical to SS_E obtained in the approximate analysis. In general, the SS_E in the exact and approximate analyses will be the same.

To test $H_0: \tau_i = 0$ the reduced model is $y_{ij} = \mu + \beta_j + \varepsilon_{ij}$. The normal equations used are:

$$\begin{array}{lclclclcl} \mu: & 15\hat{\mu} & +4\hat{\beta}_1 & +4\hat{\beta}_2 & +3\hat{\beta}_3 & +4\hat{\beta}_4 & =17 \\ \beta_1: & 4\hat{\mu} & +4\hat{\beta}_1 & & & & =-4 \\ \beta_2: & 4\hat{\mu} & & +4\hat{\beta}_2 & & & =-3 \\ \beta_3: & 3\hat{\mu} & & & +3\hat{\beta}_3 & & =6 \\ \beta_4: & 4\hat{\mu} & & & & +4\hat{\beta}_4 & =18 \end{array}$$

Applying the constraint $\sum \hat{\beta}_j = 0$, we obtain:

$$\hat{\mu} = \frac{19}{16}, \quad \hat{\beta}_1 = \frac{-35}{16}, \quad \hat{\beta}_2 = \frac{-31}{16}, \quad \hat{\beta}_3 = \frac{13}{16}, \quad \hat{\beta}_4 = \frac{53}{16}. \quad \text{Now } R(\mu, \beta) = \hat{\mu}y_{..} + \sum_{j=1}^4 \hat{\beta}_j y_{.j} = 99.25$$

with 4 degrees of freedom.

$$R(\tau | \mu, \beta) = R(\mu, \tau, \beta) - R(\mu, \beta) = 138.78 - 99.25 = 39.53 = SS_{Treatments}$$

with $7-4=3$ degrees of freedom. $R(\tau | \mu, \beta)$ is used to test $H_0: \tau_i = 0$.

The sum of squares for blocks is found from the reduced model $y_{ij} = \mu + \tau_i + \varepsilon_{ij}$. The normal equations used are:

Model Restricted to $\beta_j = 0$:

$$\begin{array}{lclclclcl} \mu: & 15\hat{\mu} & +4\hat{\tau}_1 & +3\hat{\tau}_2 & +4\hat{\tau}_3 & +4\hat{\tau}_4 & =17 \\ \tau_1: & 4\hat{\mu} & +4\hat{\tau}_1 & & & & =3 \\ \tau_2: & 3\hat{\mu} & & +3\hat{\tau}_2 & & & =1 \\ \tau_3: & 4\hat{\mu} & & & +4\hat{\tau}_3 & & =-2 \\ \tau_4: & 4\hat{\mu} & & & & +4\hat{\tau}_4 & =15 \end{array}$$

Applying the constraint $\sum \hat{\tau}_i = 0$, we obtain:

$$\hat{\mu} = \frac{13}{12}, \quad \hat{\tau}_1 = \frac{-4}{12}, \quad \hat{\tau}_2 = \frac{-9}{12}, \quad \hat{\tau}_3 = \frac{-19}{12}, \quad \hat{\tau}_4 = \frac{32}{12}$$

$$R(\mu, \tau) = \hat{\mu}y_{..} + \sum_{i=1}^4 \hat{\tau}_i y_{i.} = 59.83$$

with 4 degrees of freedom.

$$R(\beta | \mu, \tau) = R(\mu, \tau, \beta) - R(\mu, \tau) = 138.78 - 59.83 = 78.95 = SS_{Blocks}$$

with $7-4=3$ degrees of freedom.

Total	14	125.74	125.73

Note that for the exact analysis, $SS_T \neq SS_{Tips} + SS_{Blocks} + SS_E$.

4-31 An engineer is studying the mileage performance characteristics of five types of gasoline additives. In the road test he wishes to use cars as blocks; however, because of a time constraint, he must use an incomplete block design. He runs the balanced design with the five blocks that follow. Analyze the data from this experiment (use $\alpha = 0.05$) and draw conclusions.

Additive	Car				
	1	2	3	4	5
1		17	14	13	12
2	14	14		13	10
3	14		13	14	9
4	13	11	11	12	
5	11	12	10		8

There are several computer software packages that can analyze the incomplete block designs discussed in this chapter. The Minitab General Linear Model procedure is a widely available package with this capability. The output from this routine for Problem 4-27 follows. The adjusted sums of squares are the appropriate sums of squares to use for testing the difference between the means of the gasoline additives.

4-32 Construct a set of orthogonal contrasts for the data in Problem 4-31. Compute the sum of squares for each contrast.

One possible set of orthogonal contrasts is:

$$H_0 : \mu_4 + \mu_5 = \mu_1 + \mu_2 \quad (1)$$

$$H_0 : \mu_1 = \mu_2 \quad (2)$$

$$H_0 : \mu_4 = \mu_5 \quad (3)$$

$$H_0 : 4\mu_3 = \mu_4 + \mu_5 + \mu_1 + \mu_2 \quad (4)$$

The sums of squares and F -tests are:

Brand ->	1	2	3	4	5	$\sum c_i Q_i$	SS	F_0
Q_i	33/4	11/4	-3/4	-14/4	-27/4

4-34 Analyze the data in Example 4-6 using the general regression significance test.

$\mu:$	$12\hat{\mu}$	$+3\hat{\tau}_1$	$+3\hat{\tau}_2$	$+3\hat{\tau}_3$	$+3\hat{\tau}_4$	$+3\hat{\beta}_1$	$+3\hat{\beta}_2$	$+3\hat{\beta}_3$	$+3\hat{\beta}_4$	$=870$
$\tau_1:$	$3\hat{\mu}$	$+3\hat{\tau}_1$				$+\hat{\beta}_1$		$+\hat{\beta}_3$	$+\hat{\beta}_4$	$=218$
$\tau_2:$	$3\hat{\mu}$		$+3\hat{\tau}_2$				$+\hat{\beta}_2$	$+\hat{\beta}_3$	$+\hat{\beta}_4$	$=214$
$\tau_3:$	$3\hat{\mu}$			$+3\hat{\tau}_3$		$+\hat{\beta}_1$	$+\hat{\beta}_2$	$+\hat{\beta}_3$		$=216$
$\tau_4:$	$3\hat{\mu}$				$+3\hat{\tau}_4$	$+\hat{\beta}_1$	$+\hat{\beta}_2$		$+\hat{\beta}_4$	$=222$
$\beta_1:$	$3\hat{\mu}$	$+\hat{\tau}_1$		$+\hat{\tau}_3$	$+\hat{\tau}_4$	$+3\hat{\beta}_1$				$=221$
$\beta_2:$	$3\hat{\mu}$		$+\hat{\tau}_2$	$+\hat{\tau}_3$	$+\hat{\tau}_4$		$+3\hat{\beta}_2$			$=207$
$\beta_3:$	$3\hat{\mu}$	$+\hat{\tau}_1$	$+\hat{\tau}_2$	$+\hat{\tau}_3$				$+3\hat{\beta}_3$		$=224$
$\beta_4:$	$3\hat{\mu}$	$+\hat{\tau}_1$	$+\hat{\tau}_2$		$+\hat{\tau}_4$				$+3\hat{\beta}_4$	$=218$

Applying the constraints $\sum \hat{\tau}_i = \sum \hat{\beta}_j = 0$, we obtain:

$$\begin{aligned}\hat{\mu} &= 870/12, \hat{\tau}_1 = -9/8, \hat{\tau}_2 = -7/8, \hat{\tau}_3 = -4/8, \hat{\tau}_4 = 20/8, \\ \hat{\beta}_1 &= 7/8, \hat{\beta}_2 = -31/8, \hat{\beta}_3 = 24/8, \hat{\beta}_4 = 0/8 \\ R(\mu, \tau, \beta) &= \hat{\mu} y_{..} + \sum_{i=1}^4 \hat{\tau}_i y_{i..} + \sum_{j=1}^4 \hat{\beta}_j y_{..j} = 63,152.75\end{aligned}$$

with 7 degrees of freedom.

$$\begin{aligned}\sum \sum y_{ij}^2 &= 63,156.00 \\ SS_E &= \sum \sum y_{ij}^2 - R(\mu, \tau, \beta) = 63156.00 - 63152.75 = 3.25.\end{aligned}$$

To test $H_0: \tau_i = 0$ the reduced model is $y_{ij} = \mu + \beta_j + \varepsilon_{ij}$. The normal equations used are:

$\mu:$	$12\hat{\mu}$	$+3\hat{\beta}_1$	$+3\hat{\beta}_2$	$+3\hat{\beta}_3$	$+3\hat{\beta}_4$	$=870$
$\beta_1:$	$3\hat{\mu}$	$+3\hat{\beta}_1$				$=221$
$\beta_2:$	$3\hat{\mu}$		$+3\hat{\beta}_2$			$=207$
$\beta_3:$	$3\hat{\mu}$			$+3\hat{\beta}_3$		$=224$
$\beta_4:$	$3\hat{\mu}$				$+3\hat{\beta}_4$	$=218$

Applying the constraint $\sum \hat{\beta}_j = 0$, we obtain:

$$\begin{aligned}\hat{\mu} &= \frac{870}{12}, \hat{\beta}_1 = \frac{7}{6}, \hat{\beta}_2 = \frac{-21}{6}, \hat{\beta}_3 = \frac{13}{6}, \hat{\beta}_4 = \frac{1}{6} \\ R(\mu, \beta) &= \hat{\mu} y_{..} + \sum_{j=1}^4 \hat{\beta}_j y_{..j} = 63,130.00\end{aligned}$$

with 4 degrees of freedom.

$$R(\tau|\mu, \beta) = R(\mu, \tau, \beta) - R(\mu, \beta) = 63152.75 - 63130.00 = 22.75 = SS_{Treatments}$$

with $7 - 4 = 3$ degrees of freedom. $R(\tau|\mu, \beta)$ is used to test $H_0: \tau_i = 0$.

The sum of squares for blocks is found from the reduced model $y_{ij} = \mu + \tau_i + \varepsilon_{ij}$. The normal equations used are:

Model Restricted to $\beta_j = 0$:

$$\begin{array}{lclclcl} \mu: & 12\hat{\mu} & +3\hat{\tau}_1 & +3\hat{\tau}_2 & +3\hat{\tau}_3 & +3\hat{\tau}_4 & =870 \\ \tau_1: & 3\hat{\mu} & +3\hat{\tau}_1 & & & & =218 \\ \tau_2: & 3\hat{\mu} & & +3\hat{\tau}_2 & & & =214 \\ \tau_3: & 3\hat{\mu} & & & +3\hat{\tau}_3 & & =216 \\ \tau_4: & 3\hat{\mu} & & & & +3\hat{\tau}_4 & =222 \end{array}$$

The sum of squares for blocks is found as in Example 4-6. We may use the method shown above to find an adjusted sum of squares for blocks from the reduced model, $y_{ij} = \mu + \tau_i + \varepsilon_{ij}$.

4-35 Prove that $\frac{k \sum_{i=1}^a Q_i^2}{(\lambda a)}$ is the adjusted sum of squares for treatments in a BIBD.

We may use the general regression significance test to derive the computational formula for the adjusted treatment sum of squares. We will need the following:

$$\begin{aligned} \hat{\tau}_i &= \frac{kQ_i}{(\lambda a)}, \quad kQ_i = ky_{..} - \sum_{i=1}^b n_{ij}y_{.j} \\ R(\mu, \tau, \beta) &= \hat{\mu}y_{..} + \sum_{i=1}^a \hat{\tau}_i y_{i.} + \sum_{j=1}^b \hat{\beta}_j y_{.j} \end{aligned}$$

and the sum of squares we need is:

$$R(\tau|\mu, \beta) = \hat{\mu}y_{..} + \sum_{i=1}^a \hat{\tau}_i y_{i.} + \sum_{j=1}^b \hat{\beta}_j y_{.j} - \sum_{j=1}^b \frac{y_{.j}^2}{k}$$

The normal equation for β is, from equation (4-35),

$$\beta : k\hat{\mu} + \sum_{i=1}^a n_{ij}\hat{\tau}_i + k\hat{\beta}_j = y_{.j}$$

and from this we have:

$$ky_{.j}\hat{\beta}_j = y_{.j}^2 - ky_{.j}\hat{\mu} - y_{.j} \sum_{i=1}^a n_{ij}\hat{\tau}_i$$

therefore,

$$R(\tau|\mu, \beta) = \hat{\mu}y_{..} + \sum_{i=1}^a \hat{\tau}_i y_{i.} + \sum_{j=1}^b \left[\frac{y_{.j}^2}{k} - \frac{k\hat{\mu}y_{.j}}{k} - \frac{y_{.j} \sum_{i=1}^a n_{ij} \hat{\tau}_i}{k} - \frac{y_{.j}^2}{k} \right]$$

$$R(\tau|\mu, \beta) = \sum_{i=1}^a \hat{\tau}_i \left(y_{i.} - \frac{1}{k} \sum_{i=1}^a n_{ij} y_{.j} \right) = \sum_{i=1}^a Q_i \left(\frac{kQ_i}{\lambda a} \right) = k \sum_{i=1}^a \left(\frac{Q_i^2}{\lambda a} \right) \equiv SS_{Treatments(adjusted)}$$

- 4-36** An experimenter wishes to compare four treatments in blocks of two runs. Find a BIBD for this experiment with six blocks.

Treatment	Block 1	Block 2	Block 3	Block 4	Block 5	Block 6
1	X	X	X			
2	X			X	X	
3		X		X		X
4			X		X	X

Note that the design is formed by taking all combinations of the 4 treatments 2 at a time. The parameters of the design are $\lambda = 1$, $a = 4$, $b = 6$, $k = 3$, and $r = 2$

- 4-37** An experimenter wishes to compare eight treatments in blocks of four runs. Find a BIBD with 14 blocks and $\lambda = 3$.

The design has parameters $a = 8$, $b = 14$, $\lambda = 3$, $r = 2$ and $k = 4$. It may be generated from a 2^3 factorial design confounded in two blocks of four observations each, with each main effect and interaction successively confounded (7 replications) forming the 14 blocks. The design is discussed by John (1971, pg. 222) and Cochran and Cox (1957, pg. 473). The design follows:

Blocks	1=(I)	2=a	3=b	4=ab	5=c	6=ac	7=bc	8=abc
1	X		X		X		X	
2		X		X		X		X
3	X		X			X		X
4		X		X	X			X
5	X	X			X	X		
6			X	X			X	X
7	X	X					X	X
8			X	X	X	X		
9	X	X	X	X				
10					X	X	X	X
11	X			X		X	X	
12		X	X		X			X
13	X			X	X			X
14		X	X			X	X	

4-38 Perform the interblock analysis for the design in Problem 4-31.

The interblock analysis for Problem 4-31 uses $\hat{\sigma}^2 = 0.77$ and $\hat{\sigma}_\beta^2 = 2.14$. A summary of the interblock, intrablock and combined estimates is:

Parameter	Intrablock	Interblock	Combined
τ_1	2.20	-1.80	2.18
τ_2	0.73	0.20	0.73
τ_3	-0.20	-5.80	-0.23
τ_4	-0.93	9.20	-0.88
τ_5	-1.80	-1.80	-1.80

4-39 Perform the interblock analysis for the design in Problem 4-33. The interblock analysis for problem

$$4-33 \text{ uses } \hat{\sigma}^2 = 21.07 \text{ and } \sigma_\beta^2 = \frac{[MS_{Blocks(adj)} - MS_E](b-1)}{a(r-1)} = \frac{[65.68 - 21.07](6)}{7(2)} = 19.12. \quad \text{A}$$

summary of the interblock, intrablock, and combined estimates is give below

Parameter	Intrablock	Interblock	Combined
τ_1	-12.43	-11.79	-12.38
τ_2	-8.57	-4.29	-7.92
τ_3	2.57	-8.79	1.76
τ_4	10.71	9.21	10.61
τ_5	13.71	21.21	14.67
τ_6	-5.14	-22.29	-6.36
τ_7	-0.86	10.71	-0.03

4-40 Verify that a BIBD with the parameters $a = 8$, $r = 8$, $k = 4$, and $b = 16$ does not exist. These conditions imply that $\lambda = \frac{r(k-1)}{a-1} = \frac{8(3)}{7} = \frac{24}{7}$, which is not an integer, so a balanced design with these parameters cannot exist.

4-41 Show that the variance of the intra block estimators $\{\hat{\tau}_i\}$ is $\frac{k((a-1)\sigma^2)}{(\lambda a^2)}$.

Note that $\hat{\tau}_i = \frac{kQ_i}{(\lambda a)}$, and $Q_i = y_{i\cdot} - \frac{1}{k} \sum_{j=1}^b n_{ij} y_{\cdot j}$, and $kQ_i = ky_{i\cdot} - \sum_{j=1}^b n_{ij} y_{\cdot j} = (k-1)y_{i\cdot} - \left(\sum_{j=1}^b n_{ij} y_{\cdot j} - y_{i\cdot} \right)$

$y_{i\cdot}$ contains r observations, and the quantity in the parenthesis is the sum of $r(k-1)$ observations, not including treatment i . Therefore,

$$V(kQ_i) = k^2 V(Q_i) = r(k-1)^2 \sigma^2 + r(k-1)\sigma^2$$

or

$$V(Q_i) = \frac{1}{k^2} [r(k-1)\sigma^2 \{(k-1)+1\}] = \frac{r(k-1)\sigma^2}{k}$$

To find $V(\hat{\tau}_i)$, note that:

$$V(\hat{\tau}_i) = \left(\frac{k}{\lambda a}\right)^2 V(Q)_i = \left(\frac{k}{\lambda a}\right)^2 \frac{r(k-1)}{k} \sigma^2 = \frac{kr(k-1)}{(\lambda a)^2} \sigma^2$$

However, since $\lambda(a-1) = r(k-1)$, we have:

$$V(\hat{\tau}_i) = \frac{k(a-1)}{\lambda a^2} \sigma^2$$

Furthermore, the $\{\hat{\tau}_i\}$ are not independent, this is required to show that $V(\hat{\tau}_i - \hat{\tau}_j) = \frac{2k}{\lambda a} \sigma^2$

4-42 Extended incomplete block designs. Occasionally the block size obeys the relationship $a < k < 2a$. An extended incomplete block design consists of a single replicate or each treatment in each block along with an incomplete block design with $k^* = k-a$. In the balanced case, the incomplete block design will have parameters $k^* = k-a$, $r^* = r-b$, and λ^* . Write out the statistical analysis. (Hint: In the extended incomplete block design, we have $\lambda = 2r-b+\lambda^*$.)

As an example of an extended incomplete block design, suppose we have $a=5$ treatments, $b=5$ blocks and $k=9$. A design could be found by running all five treatments in each block, plus a block from the balanced incomplete block design with $k^* = k-a=9-5=4$ and $\lambda^*=3$. The design is:

Block	Complete Treatment	Incomplete Treatment
1	1,2,3,4,5	2,3,4,5
2	1,2,3,4,5	1,2,4,5
3	1,2,3,4,5	1,3,4,5
4	1,2,3,4,5	1,2,3,4
5	1,2,3,4,5	1,2,3,5

Note that $r=9$, since the augmenting incomplete block design has $r^*=4$, and $r=r^*+b=4+5=9$, and $\lambda=2r-b+\lambda^*=18-5+3=16$. Since some treatments are repeated in each block it is possible to compute an error sum of squares between repeat observations. The difference between this and the residual sum of squares is due to interaction. The analysis of variance table is shown below:

Source	SS	DF
Treatments (adjusted)	$k \sum \frac{Q_i^2}{a\lambda}$	$a-1$
Blocks	$\sum \frac{y_{..j}^2}{k} - \frac{y_{..}^2}{N}$	$b-1$
Interaction	Subtraction	$(a-1)(b-1)$
Error	[SS between repeat observations]	$b(k-a)$

$$\text{Total} \quad \sum \sum y_{ij}^2 - \frac{y_{..}^2}{N} \quad N-1$$

Chapter 5

Introduction to Factorial Designs

Solutions

5-1 The yield of a chemical process is being studied. The two most important variables are thought to be the pressure and the temperature. Three levels of each factor are selected, and a factorial experiment with two replicates is performed. The yield data follow:

Temperature	Pressure		
	200	215	230
150	90.4	90.7	90.2
	90.2	90.6	90.4
160	90.1	90.5	89.9
	90.3	90.6	90.1
170	90.5	90.8	90.4
	90.7	90.9	90.1

(a) Analyze the data and draw conclusions. Use $\alpha = 0.05$.

Both pressure (A) and temperature (B) are significant, the interaction is not.

Design Expert Output

Response:Surface Finish

ANOVA for Selected Factorial Model

Analysis of variance table [Partial sum of squares]

Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	1.14	8	0.14	8.00	0.0026	significant
<i>A</i>	0.77	2	0.38	21.59	0.0004	
<i>B</i>	0.30	2	0.15	8.47	0.0085	
<i>AB</i>	0.069	4	0.017	0.97	0.4700	
Residual	0.16	9	0.018			
Lack of Fit	0.000	0				
Pure Error	0.16	9	0.018			
Cor Total	1.30	17				

The Model F-value of 8.00 implies the model is significant. There is only a 0.26% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant.

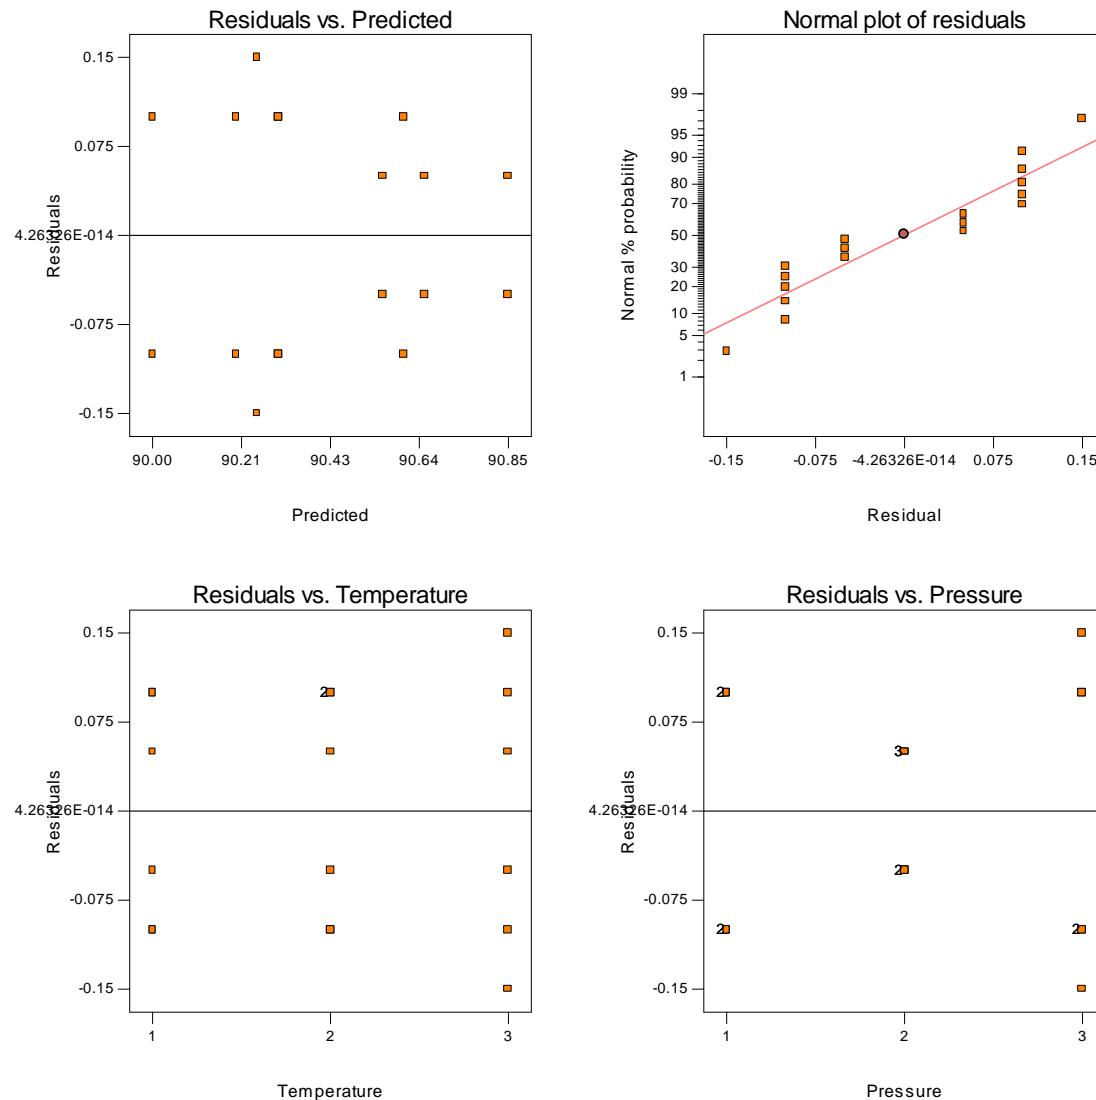

In this case A, B are significant model terms.

Values greater than 0.1000 indicate the model terms are not significant.

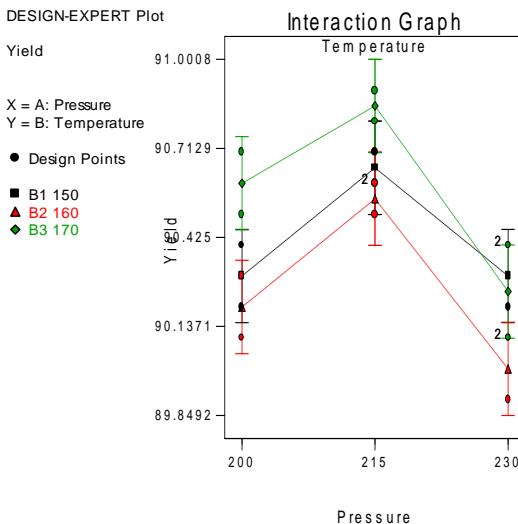

If there are many insignificant model terms (not counting those required to support hierarchy), model reduction may improve your model.

(b) Prepare appropriate residual plots and comment on the model's adequacy.

The residual plots show no serious deviations from the assumptions.

(c) Under what conditions would you operate this process?

Set pressure at 215 and Temperature at the high level, 170 degrees C, as this gives the highest yield.

The standard analysis of variance treats all design factors as if they were qualitative. In this case, both factors are quantitative, so some further analysis can be performed. In Section 5-5, we show how response curves and surfaces can be fit to the data from a factorial experiment with at least one quantitative factor. Since both factors in this problem are quantitative and have three levels, we can fit linear and quadratic effects of both temperature and pressure, exactly as in Example 5-5 in the text. The Design-Expert output, including the response surface plots, now follows.

Design Expert Output

Response:Surface Finish

ANOVA for Selected Factorial Model

Analysis of variance table [Partial sum of squares]

Source	Sum of Squares	DF	Mean Square	F Value	Prob > F

Final Equation in Terms of Actual Factors:

$$\text{Yield} = +48.54630 + 0.86759 * \text{Pressure} - 0.64042 * \text{Temperature} - 1.81481E-003 * \text{Pressure}^2 + 2.41667E-003 * \text{Temperature}^2 - 5.83333E-004 * \text{Pressure} * \text{Temperature}$$

5-2 An engineer suspects that the surface finish of a metal part is influenced by the feed rate and the depth of cut. She selects three feed rates and four depths of cut. She then conducts a factorial experiment and obtains the following data:

Feed Rate (in/min)	Depth of Cut (in)			
	0.15	0.18	0.20	0.25
0.20	74	79	82	99
	64	68	88	104
	60	73	92	96
	92	98	99	104

	0.25	86	104	108	110
		88	88	95	99
			99	104	108
	0.30	98	99	110	111
		102	95	99	107

(a) Analyze the data and draw conclusions. Use $\alpha = 0.05$.

The depth (A) and feed rate (B) are significant, as is the interaction (AB).

Residual	689.33	24	28.72			
Lack of Fit	0.000	0				
Pure Error	689.33	24	28.72			
Cor Total	6532.00	35				

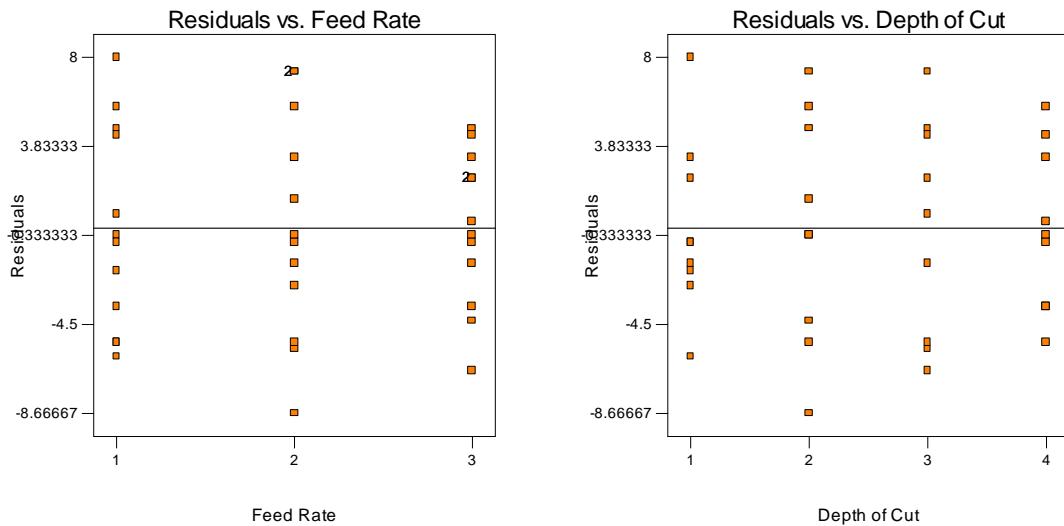

The Model F-value of 18.49 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant. In this case A, B, AB are significant model terms.

(b) Prepare appropriate residual plots and comment on the model's adequacy.

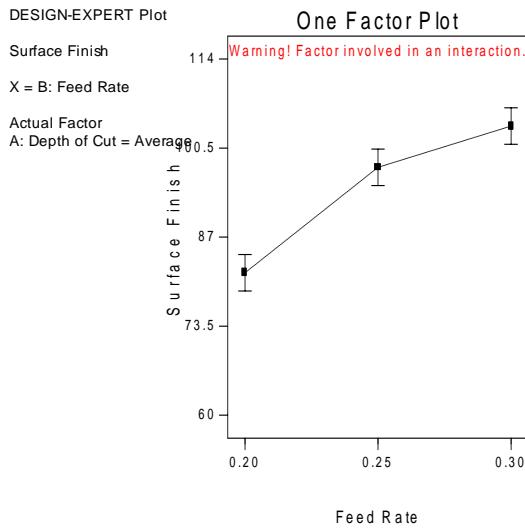

The residual plots shown indicate nothing unusual.

(c) Obtain point estimates of the mean surface finish at each feed rate.

Feed Rate	Average
0.20	81.58
0.25	97.58
0.30	103.83

(d) Find P -values for the tests in part (a).

The P -values are given in the computer output in part (a).

5-3 For the data in Problem 5-2, compute a 95 percent interval estimate of the mean difference in response for feed rates of 0.20 and 0.25 in/min.

We wish to find a confidence interval on $\mu_1 - \mu_2$, where μ_1 is the mean surface finish for 0.20 in/min and μ_2 is the mean surface finish for 0.25 in/min.

$$\bar{y}_{1..} - \bar{y}_{2..} - t_{\alpha/2, ab(n-1)} \sqrt{\frac{2MS_E}{n}} \leq \mu_1 - \mu_2 \leq \bar{y}_{1..} - \bar{y}_{2..} + t_{\alpha/2, ab(n-1)} \sqrt{\frac{2MS_E}{n}}$$

$$(81.5833 - 97.5833) \pm (2.064) \sqrt{\frac{2(28.7222)}{3}} = -16 \pm 9.032$$

Therefore, the 95% confidence interval for $\mu_1 - \mu_2$ is -16.000 ± 9.032 .

5-4 An article in *Industrial Quality Control* (1956, pp. 5-8) describes an experiment to investigate the effect of the type of glass and the type of phosphor on the brightness of a television tube. The response variable is the current necessary (in microamps) to obtain a specified brightness level. The data are as follows:

Glass Type	Phosphor Type		
	1	2	3
1	280	300	290
	290	310	285
	285	295	290
2	230	260	220
	235	240	225
	240	235	230

(a) Is there any indication that either factor influences brightness? Use $\alpha = 0.05$.

Both factors, phosphor type (*A*) and Glass type (*B*) influence brightness.

Design Expert Output

Response: Current in microamps

ANOVA for Selected Factorial Model

Analysis of variance table [Partial sum of squares]

Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	15516.67	5	3103.33	58.80	< 0.0001	significant
<i>A</i>	933.33	2	466.67	8.84	0.0044	
<i>B</i>	14450.00	1	14450.00	273.79	< 0.0001	
<i>AB</i>	133.33	2	66.67	1.26	0.3178	
Residual	633.33	12	52.78			
<i>Lack of Fit</i>	0.000	0				
Pure Error	633.33	12	52.78			
Cor Total	16150.00	17				

The Model F-value of 58.80 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

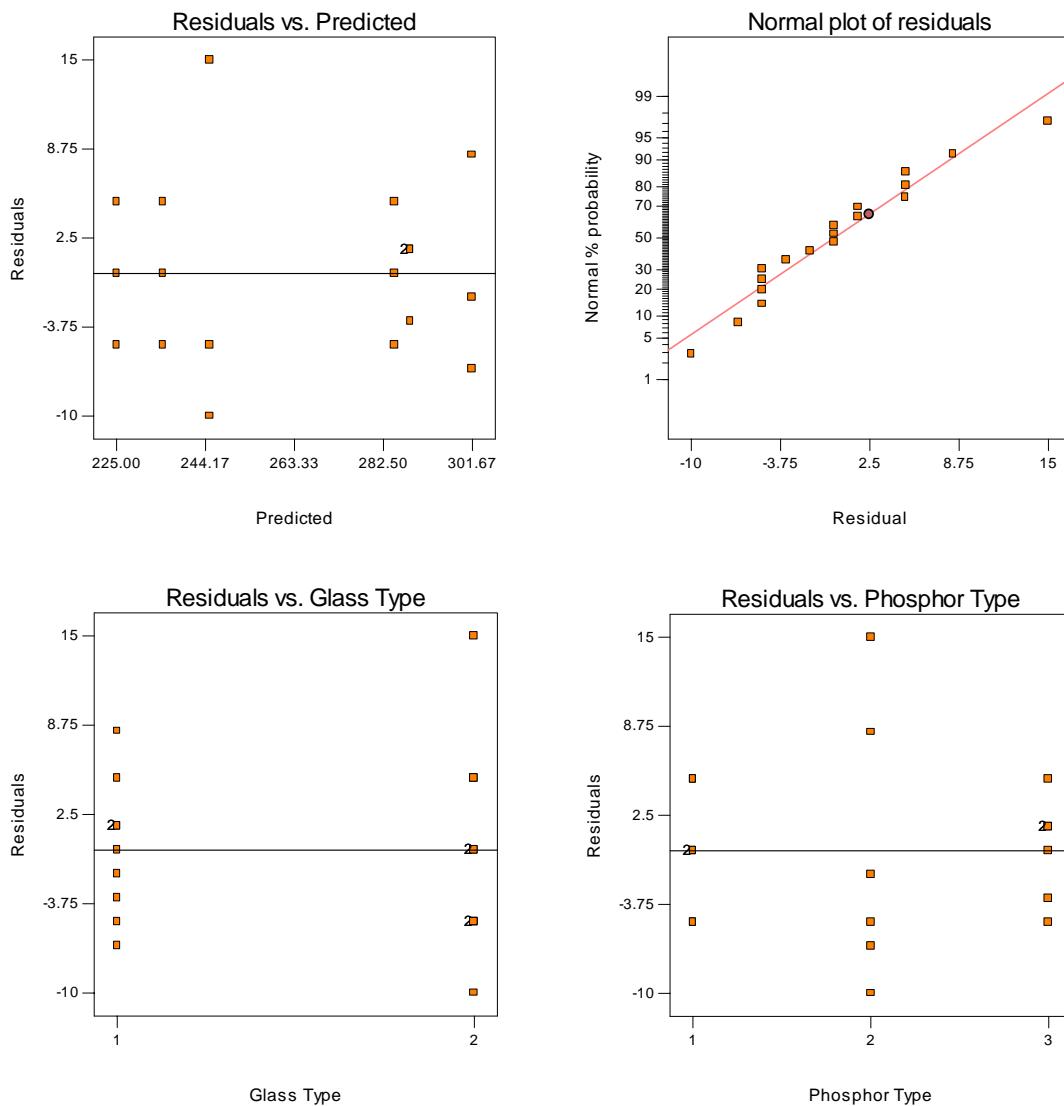

Values of "Prob > F" less than 0.0500 indicate model terms are significant.
In this case A, B are significant model terms.

(b) Do the two factors interact? Use $\alpha = 0.05$.

There is no interaction effect.

(c) Analyze the residuals from this experiment.

The residual plot of residuals versus phosphor content indicates a very slight inequality of variance. It is not serious enough to be of concern, however.

5-5 Johnson and Leone (*Statistics and Experimental Design in Engineering and the Physical Sciences*, Wiley 1977) describe an experiment to investigate the warping of copper plates. The two factors studies were the temperature and the copper content of the plates. The response variable was a measure of the amount of warping. The data were as follows:

Temperature (°C)	Copper Content (%)			
	40	60	80	100
50	17,20	16,21	24,22	28,27
75	12,9	18,13	17,12	27,31
100	16,12	18,21	25,23	30,23
125	21,17	23,21	23,22	29,31

- (a) Is there any indication that either factor affects the amount of warping? Is there any interaction between the factors? Use $\alpha = 0.05$.

Both factors, copper content (A) and temperature (B) affect warping, the interaction does not.

Design Expert Output

Response: Warping

ANOVA for Selected Factorial Model

Analysis of variance table [Partial sum of squares]

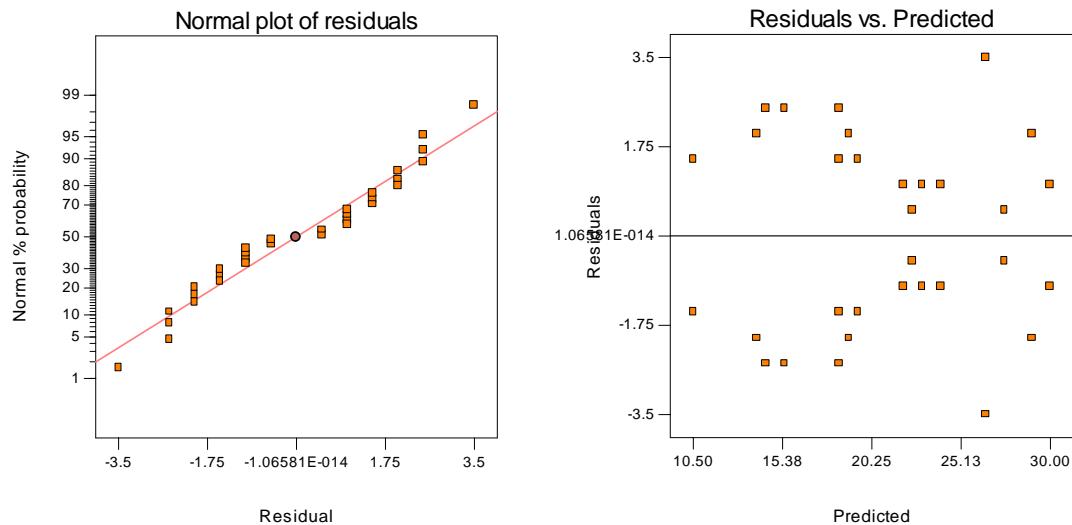

Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	968.22	15	64.55	9.52	< 0.0001	significant

Analysis of variance table [Partial sum of squares]

Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	0.28	7	0.040	15.53	0.0005	significant
A	0.15	1	0.15	57.01	< 0.0001	
B	0.092	3	0.031	11.86	0.0026	
AB	0.042	3	0.014	5.37	0.0256	
Residual	0.021	8	2.600E-003			
Lack of Fit	0.000	0				
Pure Error	0.021	8	2.600E-003			
Cor Total	0.30	15				

The Model F-value of 15.53 implies the model is significant.

There is only a 0.05% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant.
In this case A, B, AB are significant model terms.

The factors speed and feed rate, as well as the interaction is important.

The standard analysis of variance treats all design factors as if they were qualitative. In this case, both factors are quantitative, so some further analysis can be performed. In Section 5-5, we show how response curves and surfaces can be fit to the data from a factorial experiment with at least one quantitative factor. Since both factors in this problem are quantitative, we can fit polynomial effects of both speed and feed rate, exactly as in Example 5-5 in the text. The Design-Expert output with only the significant terms retained, including the response surface plots, now follows.

Design Expert Output

B2	0.13	0.045	0.036	0.23	1.00

Final Equation in Terms of Coded Factors:

$$\begin{aligned} \text{Force} &= \\ &+2.69 \\ &+0.096 * A \\ &+0.047 * B \\ &+0.13 * B^2 \end{aligned}$$

Final Equation in Terms of Actual Factors:

$$\begin{aligned} \text{Force} &= \\ &+2.48917 \\ &+3.06667E-003 * \text{Drill Speed} \\ &-15.76667 * \text{Feed Rate} \\ &+266.66667 * \text{Feed Rate}^2 \end{aligned}$$

5-8 An experiment is conducted to study the influence of operating temperature and three types of face-plate glass in the light output of an oscilloscope tube. The following data are collected:

Glass Type	Temperature		
	100	125	150
1	580	1090	1392
	568	1087	1380
	570	1085	1386
2	550	1070	1328
	530	1035	1312
	579	1000	1299
3	546	1045	867
	575	1053	904
	599	1066	889

Use $\alpha = 0.05$ in the analysis. Is there a significant interaction effect? Does glass type or temperature affect the response? What conclusions can you draw? Use the method discussed in the text to partition the temperature effect into its linear and quadratic components. Break the interaction down into appropriate components.

5-9 Consider the data in Problem 5-1. Use the method described in the text to compute the linear and quadratic effects of pressure.

See the alternative analysis shown in Problem 5-1 part (c).

5-10 Use Duncan's multiple range test to determine which levels of the pressure factor are significantly different for the data in Problem 5-1.

$$\bar{y}_{.3.} = 90.18 \quad \bar{y}_{.1.} = 90.37 \quad \bar{y}_{.2.} = 90.68$$

$$S_{y_{j.}} = \sqrt{\frac{MS_E}{an}} = \sqrt{\frac{0.01777}{(3)(2)}} = 0.0543$$

$$r_{0.01}(2,9) = 4.60 \quad r_{0.01}(3,9) = 4.86$$

$$R_2 = (4.60)(0.0543) = 0.2498 \quad R_3 = (4.86)(0.0543) = 0.2640$$

$$2 \text{ vs. } 3 = 0.50 > 0.2640 \quad (R_3)$$

$$2 \text{ vs. } 1 = 0.31 > 0.2498 \quad (R_2)$$

$$1 \text{ vs. } 3 = 0.19 < 0.2498 \quad (R_2)$$

Therefore, 2 differs from 1 and 3.

5-11 An experiment was conducted to determine if either firing temperature or furnace position affects the baked density of a carbon anode. The data are shown below.

Position	Temperature (°C)		
	800	825	850
1	570	1063	565
	565	1080	510
	583	1043	590
2	528	988	526
	547	1026	538
	521	1004	532

Suppose we assume that no interaction exists. Write down the statistical model. Conduct the analysis of variance and test hypotheses on the main effects. What conclusions can be drawn? Comment on the model's adequacy.

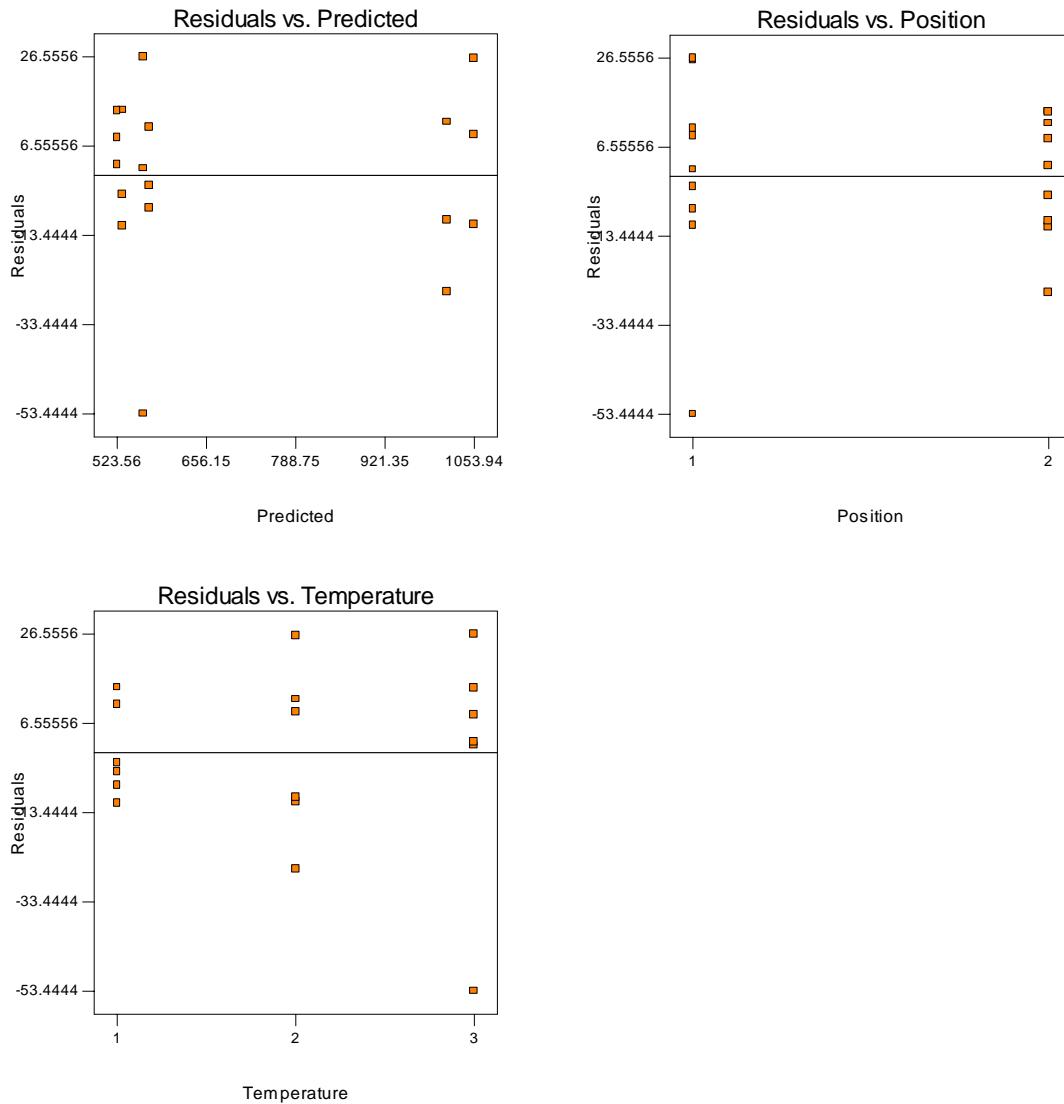

The model for the two-factor, no interaction model is $y_{ijk} = \mu + \tau_i + \beta_j + \varepsilon_{ijk}$. Both factors, furnace position (A) and temperature (B) are significant. The residual plots show nothing unusual.

<i>Lack of Fit</i>	0.000	0			
<i>Pure Error</i>	6.58	18	0.37		
Cor Total	66.31	35			

The Model F-value of 9.61 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant. In this case A, B, C, AC are significant model terms.

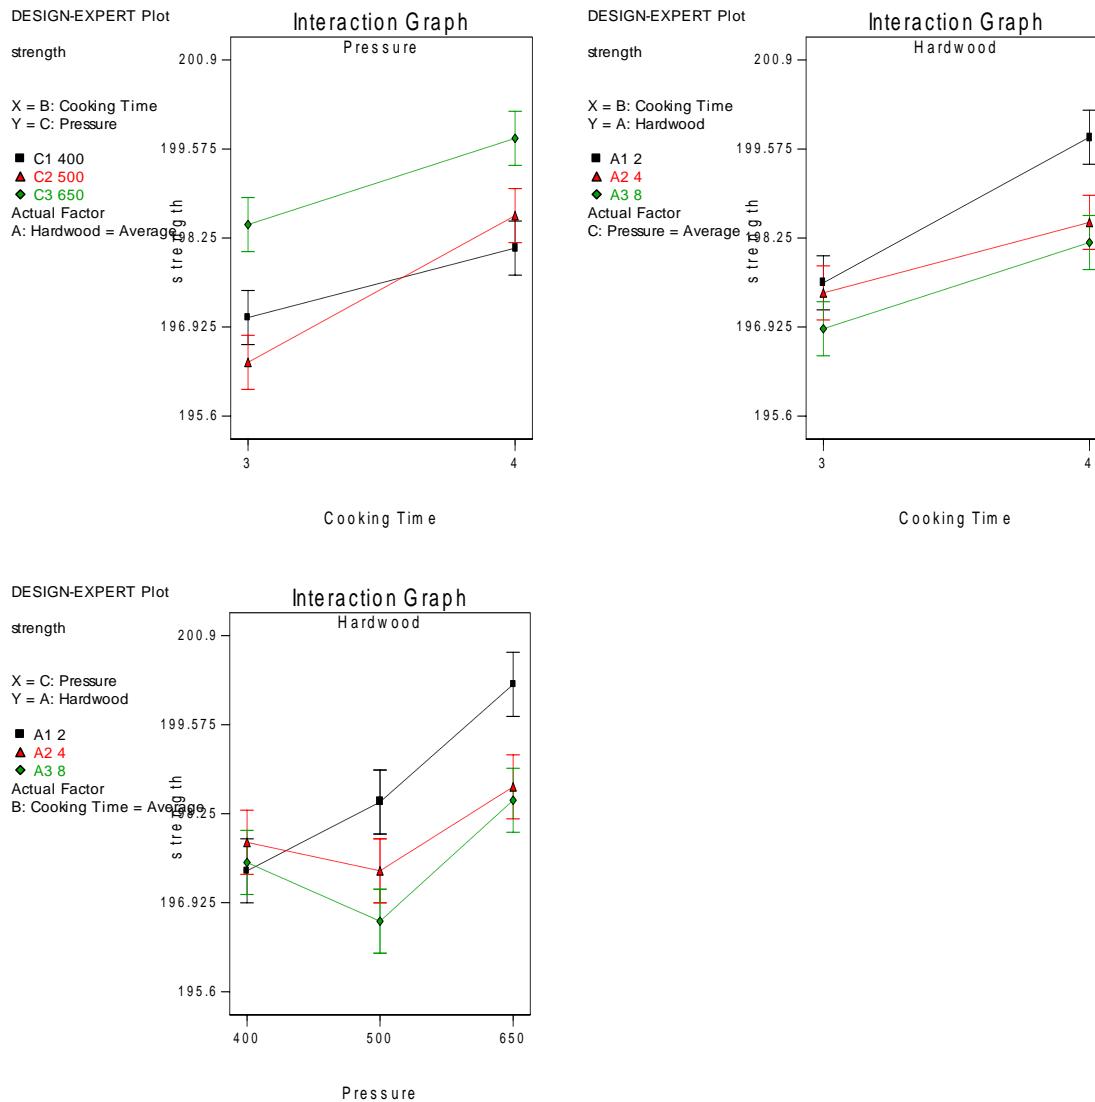

All three main effects, concentration (*A*), pressure (*C*) and time (*B*), as well as the concentration x pressure interaction (*AC*) are significant at the 5% level. The concentration x time (*AB*) and pressure x time interactions (*BC*) are significant at the 10% level.

(b) Prepare appropriate residual plots and comment on the model's adequacy.

There is nothing unusual about the residual plots.

(c) Under what set of conditions would you run the process? Why?

For the highest strength, run the process with the percentage of hardwood at 2, the pressure at 650, and the time at 4 hours.

The standard analysis of variance treats all design factors as if they were qualitative. In this case, all three factors are quantitative, so some further analysis can be performed. In Section 5-5, we show how response curves and surfaces can be fit to the data from a factorial experiment with at least one quantitative factor. Since the factors in this problem are quantitative and two of them have three levels, we can fit a linear term for the two-level factor and linear and quadratic components for the three-level factors. The Minitab output, with the *ABC* interaction removed due to insignificance, now follows. Also included is the Design Expert output; however, if the student chooses to use Design Expert, sequential sum of squares must be selected to assure that the sum of squares for the model equals the total of the sum of squares for each factor included in the model.

Cor Total	66.31	35				

The Model F-value of 12.71 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant.

In this case A, B, C², AC, A²C, AC², BC² are significant model terms.

Values greater than 0.1000 indicate the model terms are not significant.

If there are many insignificant model terms (not counting those required to support hierarchy), model reduction may improve your model.

5-17 The quality control department of a fabric finishing plant is studying the effect of several factors on the dyeing of cotton-synthetic cloth used to manufacture men's shirts. Three operators, three cycle times, and two temperatures were selected, and three small specimens of cloth were dyed under each set of conditions. The finished cloth was compared to a standard, and a numerical score was assigned. The results follow. Analyze the data and draw conclusions. Comment on the model's adequacy.

Cycle Time	Temperature						
	300°			350°			
	Operator			Operator			
40	1	23	27	31	24	38	34
	2	24	28	32	23	36	36
	3	25	26	29	28	35	39
50	1	36	34	33	37	34	34
	2	35	38	34	39	38	36
	3	36	39	35	35	36	31
60	1	28	35	26	26	36	28
	2	24	35	27	29	37	26
	3	27	34	25	25	34	24

All three main effects, and the AB , AC , and ABC interactions are significant. There is nothing unusual about the residual plots.

The Model F-value of 22.24 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant. In this case A, B, C, AB, AC, ABC are significant model terms.

5-18 In Problem 5-1, suppose that we wish to reject the null hypothesis with a high probability if the difference in the true mean yield at any two pressures is as great as 0.5. If a reasonable prior estimate of the standard deviation of yield is 0.1, how many replicates should be run?

$$\Phi^2 = \frac{n a D^2}{2 b \sigma^2} = \frac{n(3)(0.5)^2}{2(3)(0.1)^2} = 12.5n$$

n	Φ^2	Φ	$v_1 = (b-1)$	$v_2 = ab(n-1)$	β
2	25	5	2	(3)(3)(1)	0.014

2 replications will be enough to detect the given difference.

5-19 The yield of a chemical process is being studied. The two factors of interest are temperature and pressure. Three levels of each factor are selected; however, only 9 runs can be made in one day. The experimenter runs a complete replicate of the design on each day. The data are shown in the following table. Analyze the data assuming that the days are blocks.

Temperature	Day 1			Day 2				
	Pressure	250	260	270	Pressure	250	260	270
Low	86.3	84.0	85.8	86.1	85.2	87.3		
Medium	88.5	87.3	89.0	89.4	89.9	90.3		
High	89.1	90.2	91.3	91.7	93.2	93.7

	2.06	3.96	3.98
	2.38	3.64	3.24
0.1	2.24	11.00	9.96
	2.71	11.00	10.01
	2.81	9.06	9.36
	2.08	11.30	10.40

(a) Analyze the data from this experiment (use $\alpha = 0.05$).

Design Expert Output

Response: Crack Growth

ANOVA for Selected Factorial Model

Analysis of variance table [Partial sum of squares]

Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	376.11	8	47.01	234.02	< 0.0001	significant
<i>A</i>	209.89	2	104.95	522.40	< 0.0001	
<i>B</i>	64.25	2	32.13	159.92	< 0.0001	
<i>AB</i>	101.97	4	25.49	126.89	< 0.0001	
Residual	5.42	27	0.20			
Lack of Fit	0.000	0				
Pure Error	5.42	27	0.20			
Cor Total	381.53	35				

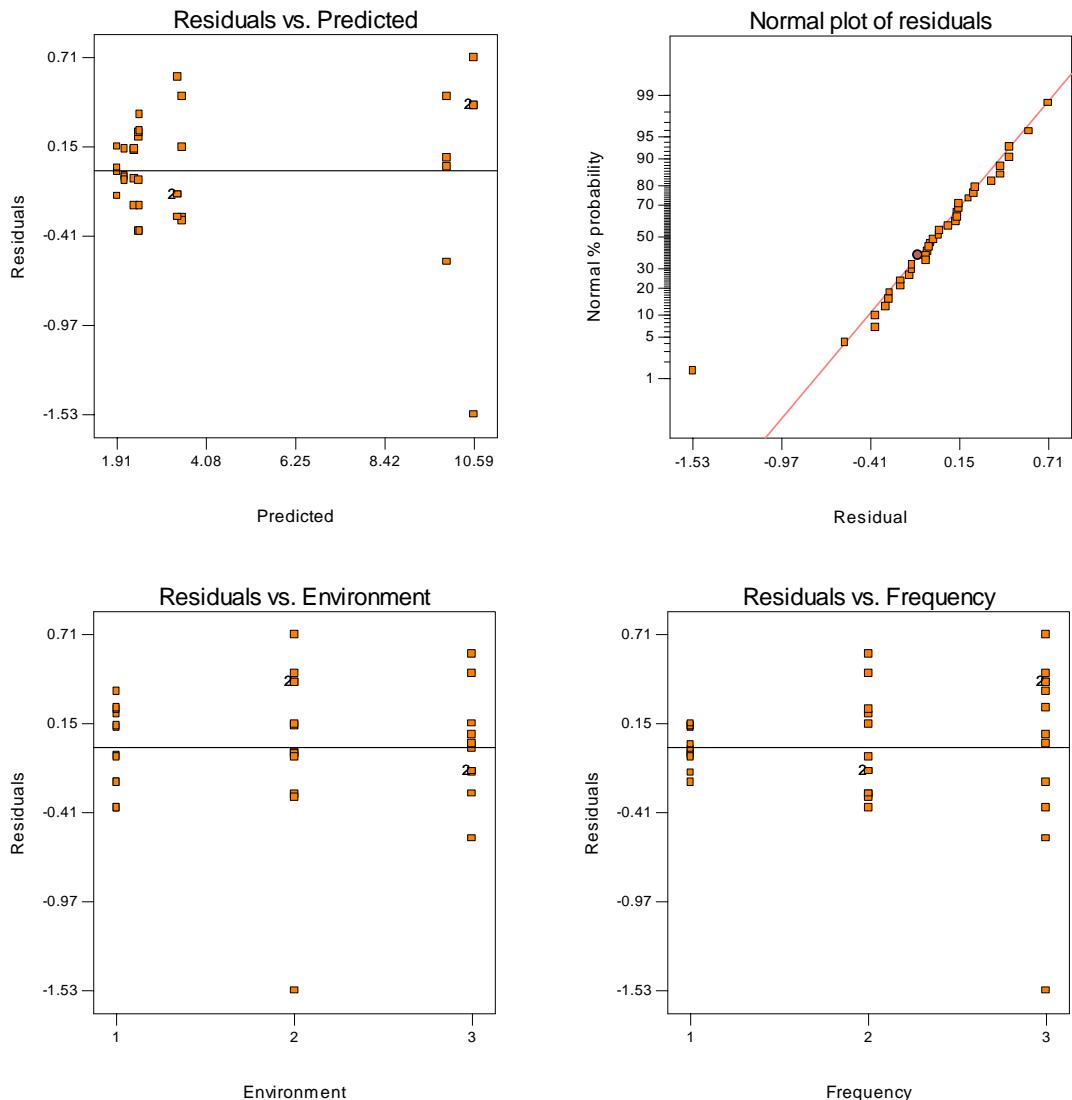

The Model F-value of 234.02 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant. In this case A, B, AB are significant model terms.

Both frequency and environment, as well as their interaction are significant.

(b) Analyze the residuals.

The residual plots indicate that there may be some problem with inequality of variance. This is particularly noticeable on the plot of residuals versus predicted response and the plot of residuals versus frequency.

(c) Repeat the analyses from parts (a) and (b) using $\ln(y)$ as the response. Comment on the results.

Lack of Fit	0.000	0							
Pure Error	0.25	27	9.367E-003						
Cor Total	13.71	35							

The Model F-value of 179.57 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant.
In this case A, B, AB are significant model terms.

Both frequency and environment, as well as their interaction are significant. The residual plots of the based on the transformed data look better.

5-23 An article in the *IEEE Transactions on Electron Devices* (Nov. 1986, pp. 1754) describes a study on polysilicon doping. The experiment shown below is a variation of their study. The response variable is base current.

Polysilicon Doping (ions)	Anneal Temperature (°C)		
	900	950	1000
1×10^{20}	4.60	10.15	11.01
	4.40	10.20	10.58
2×10^{20}	3.20	9.38	10.81
	3.50	10.02	10.60

- (a) Is there evidence (with $\alpha = 0.05$) indicating that either polysilicon doping level or anneal temperature affect base current?

Design Expert Output

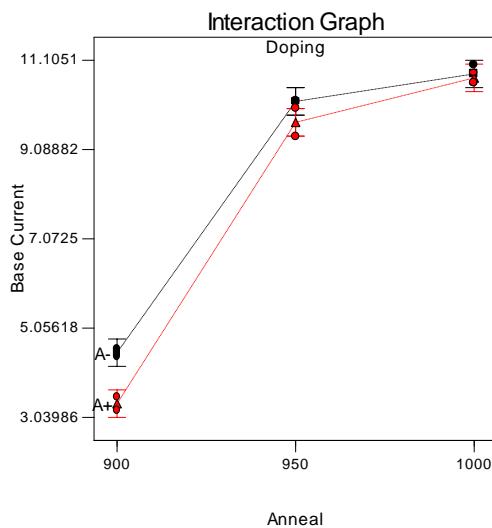

Response: Base Current					
ANOVA for Selected Factorial Model					
Analysis of variance table [Partial sum of squares]					
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F
Model	112.74	5	22.55	350.91	< 0.0001

Life

ANOVA for Selected Factorial Model

Analysis of variance table [Terms added sequentially (first to last)]

Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	23.33	5	4.67	54.36	< 0.0001	significant
A	0.80	1	0.80	9.33	0.0224	
B	22.45	2	11.22	130.75	< 0.0001	
AB	0.082	2	0.041	0.48	0.6430	
Pure Error	0.52	6	0.086			
Cor Total	23.84	11				

The Model F-value of 54.36 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant.

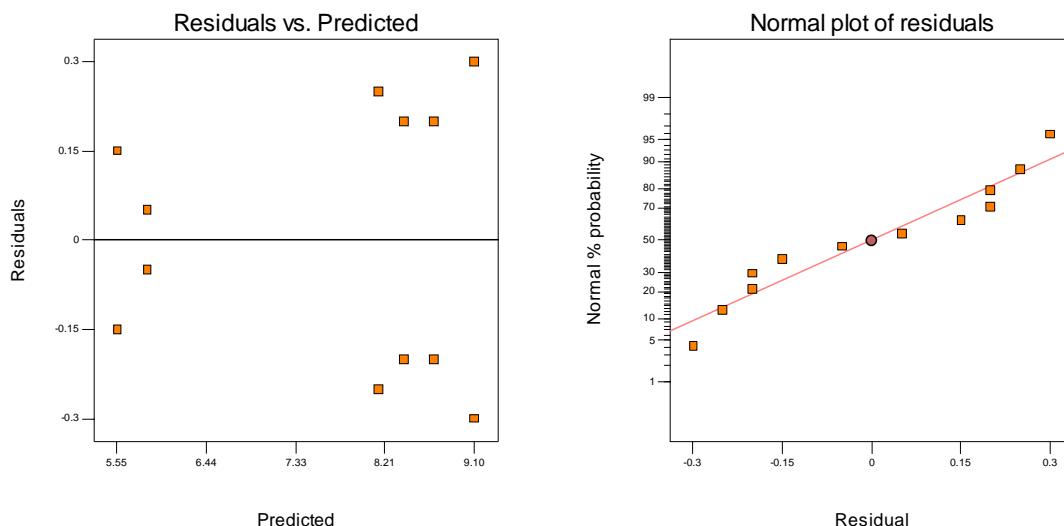

In this case A, B are significant model terms.

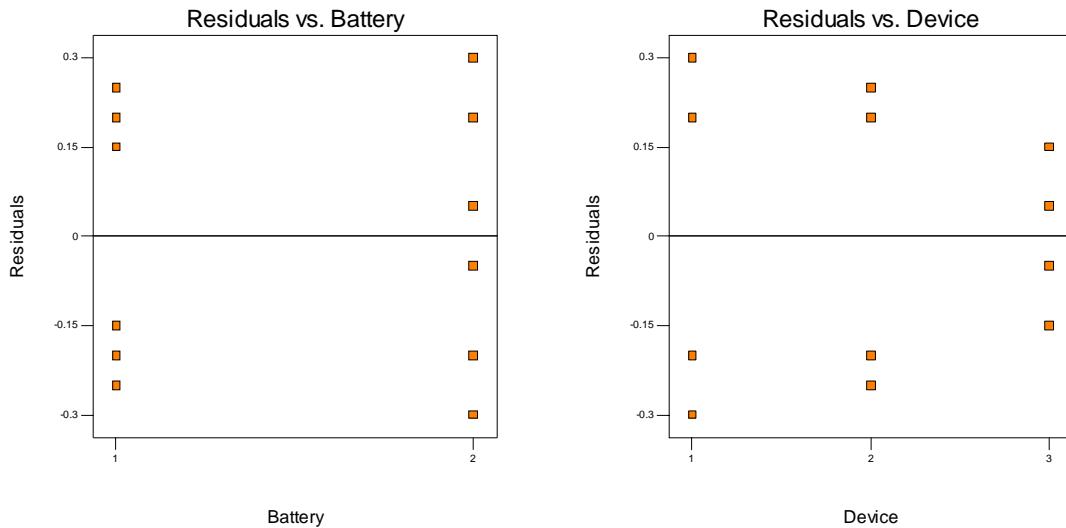

Values greater than 0.1000 indicate the model terms are not significant.

If there are many insignificant model terms (not counting those required to support hierarchy), model reduction may improve your model.

(b) Investigate model adequacy by plotting the residuals.

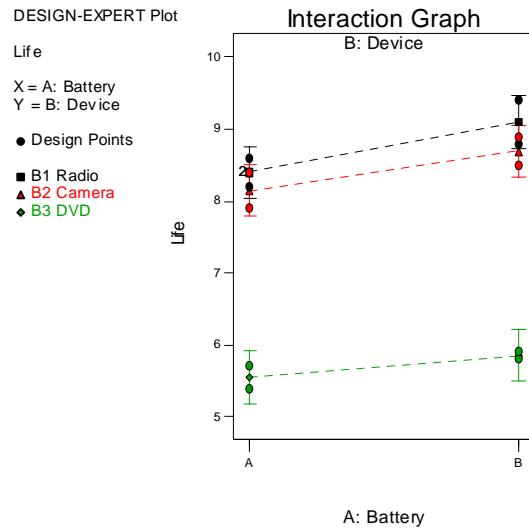

The residual plots show no serious deviations from the assumptions.

(c) Which brand of batteries would you recommend?

Battery brand B is recommended.

5-25 The author has recently purchased new golf clubs, which he believes will significantly improve his game. Below are the scores of three rounds of golf played at three different golf courses with the old and the new clubs.

Clubs	Course		
	Ahwatukee	Karsten	Foothills
Old	90	91	88
	87	93	86
	86	90	90
New	88	90	86
	87	91	85

85

88

88

- (a) Conduct an analysis of variance. Using $\alpha = 0.05$, what conclusions can you draw?

Although there is a significant difference between the golf courses, there is not a significant difference between the old and new clubs.

Design Expert Output

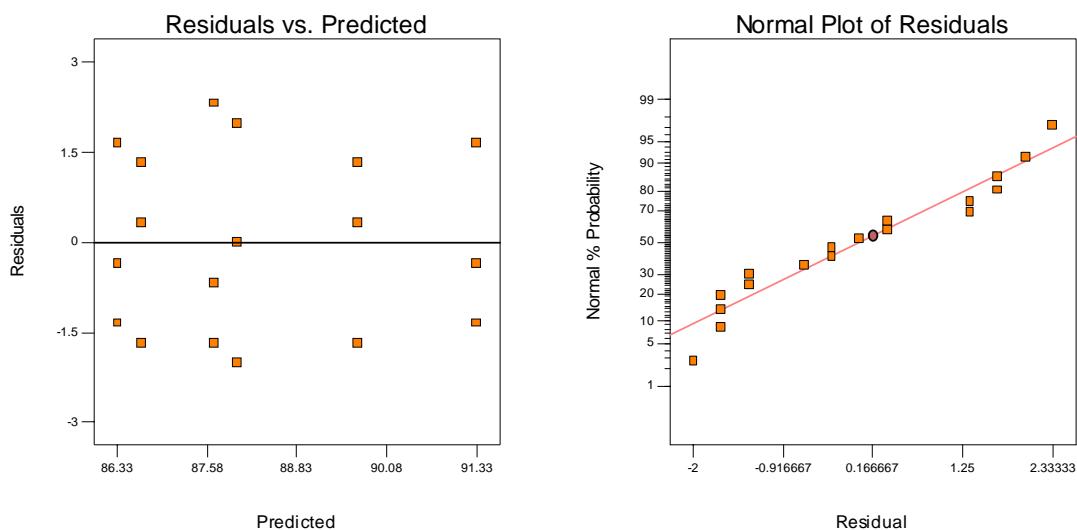

Response: Score					
ANOVA for Selected Factorial Model					
Analysis of variance table [Terms added sequentially (first to last)]					
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F
Model	54.28	5	10.86	3.69	0.0297
A	9.39	1	9.39	3.19	0.0994
B	44.44	2	22.22	7.55	0.0075
AB	0.44	2	0.22	0.075	0.9277
Pure Error	35.33	12	2.94		
Cor Total	89.61	17			

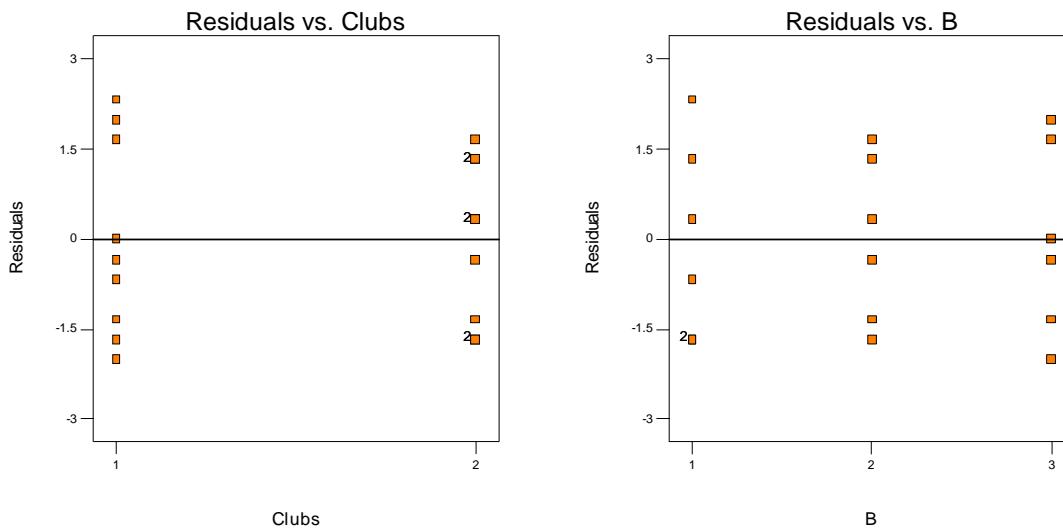

The Model F-value of 3.69 implies the model is significant. There is only a 2.97% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant.
In this case B are significant model terms.
Values greater than 0.1000 indicate the model terms are not significant.
If there are many insignificant model terms (not counting those required to support hierarchy), model reduction may improve your model.

- (b) Investigate model adequacy by plotting the residuals.

The residual plots show no deviations from the assumptions.

5-26 A manufacturer of laundry products is investigating the performance of a newly formulated stain remover. The new formulation is compared to the original formulation with respect to its ability to remove a standard tomato-like stain in a test article of cotton cloth using a factorial experiment. The other factors in the experiment are the number of times the test article is washed (1 or 2), and whether or not a detergent booster is used. The response variable is the stain shade after washing (12 is the darkest, 0 is the lightest). The data are shown in the table below.

Formulation	Number of Washings		Number of Washings	
	1		2	
	Booster		Booster	
New	Yes	No	Yes	No
	6	6	3	4
Original	5	5	2	1
	10	11	10	9
	9	11	9	10

- (a) Conduct an analysis of variance. Using $\alpha = 0.05$, what conclusions can you draw?

The formulation, number of washings, and the interaction between these two factors appear to be significant. Continued analysis is required as a result of the residual plots in part (b). Conclusions are presented in part (b).

Design Expert Output

ANOVA for Selected Factorial Model						
Analysis of variance table [Terms added sequentially (first to last)]						
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F

C	0.56	1	0.56	0.60	0.4609	
AB	5.06	1	5.06	5.40	0.0486	
AC	0.56	1	0.56	0.60	0.4609	
BC	0.56	1	0.56	0.60	0.4609	

<i>ABC</i>	0.56	1	0.56	0.60	0.4609
<i>Pure Error</i>	7.50	8	0.94		
Cor Total	166.94	15			

The Model F-value of 24.30 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant.

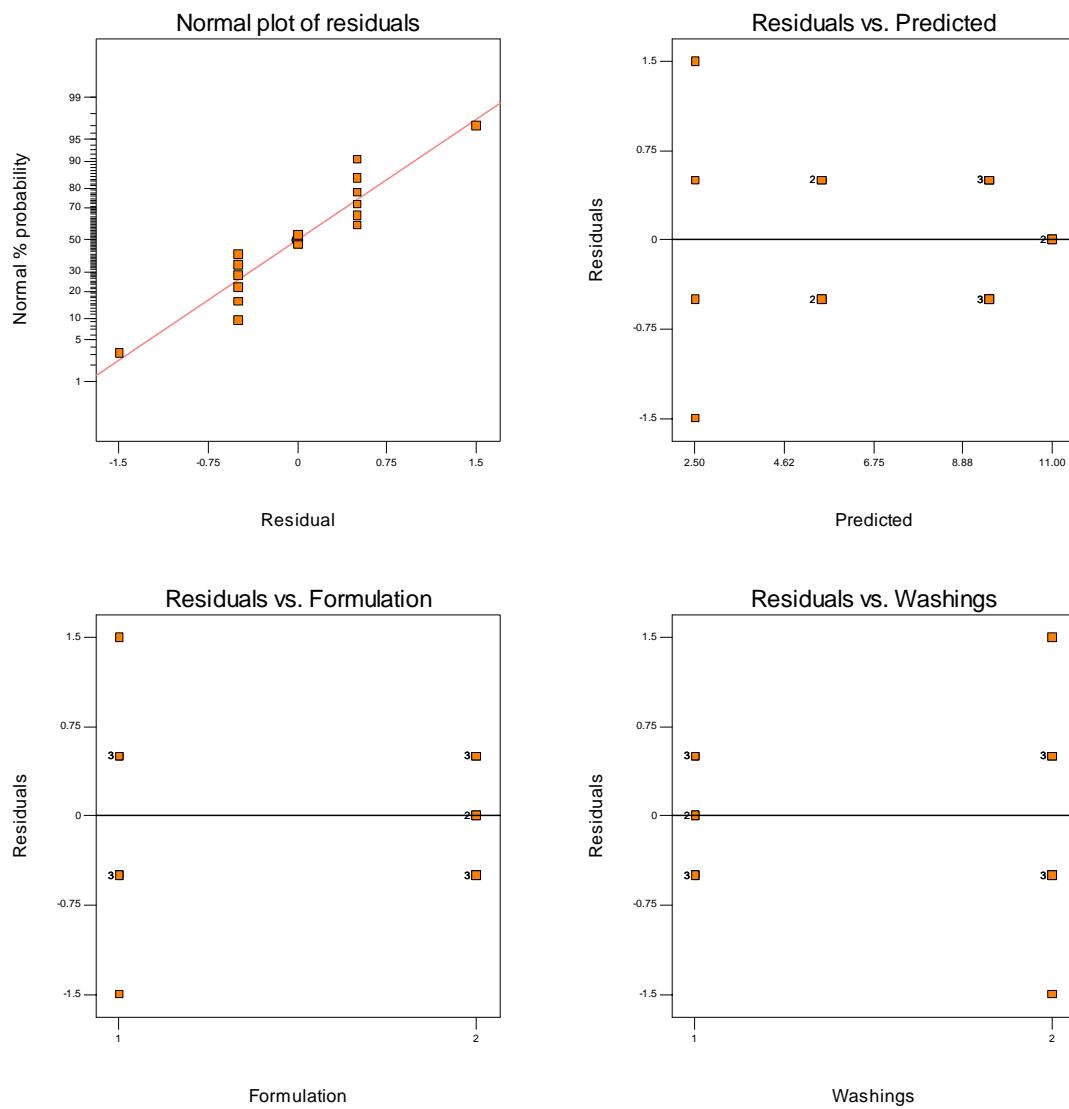

In this case A, B, AB are significant model terms.

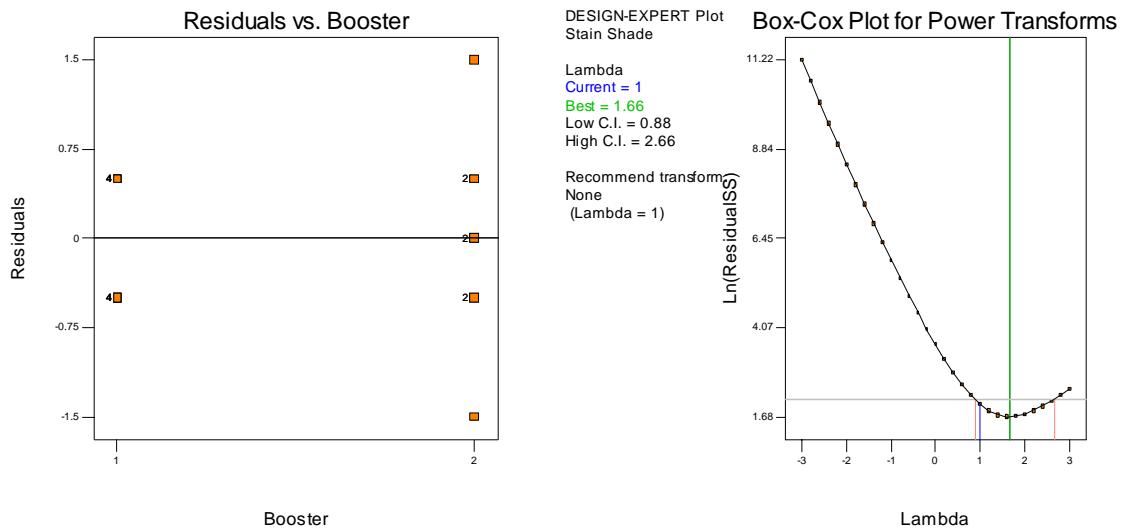

Values greater than 0.1000 indicate the model terms are not significant.

If there are many insignificant model terms (not counting those required to support hierarchy), model reduction may improve your model.

(b) Investigate model adequacy by plotting the residuals.

The residual plots shown below identify a violation from our assumptions; nonconstant variance. A power transformation was chosen to correct the violation. λ can be found through trial and error; or the use of a Box-Cox plot that is described in a later chapter. A Box-Cox plot is shown below that identifies a power transformation λ of 1.66.

The analysis of variance was performed with the transformed data and is shown below. This time, only the formulation and number of washings appear to be significant; the interaction between these two factors is no longer significant after the data transformation. The residual plots show no deviations from the assumptions. The plot of the effects below identifies the new formulation along with two washings produces the best results. The booster is not significant.

The Model F-value of 38.18 implies the model is significant. There is only a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant.

In this case A, B, are significant model terms.

Values greater than 0.1000 indicate the model terms are not significant.

If there are many insignificant model terms (not counting those required to support hierarchy), model reduction may improve your model.

Chapter 9

Three-Level and Mixed-Level Factorial and Fractional Factorial Design Solutions

9-1 The effects of developer concentration (A) and developer time (B) on the density of photographic plate film are being studied. Three strengths and three times are used, and four replicates of a 3^2 factorial experiment are run. The data from this experiment follow. Analyze the data using the standard methods for factorial experiments.

Developer Concentration	Development Time (minutes)		
	10	14	18
10%	0	2	1
	5	4	2
12%	4	6	8
	7	5	7
14%	7	10	10
	8	7	9

Design Expert Output

Cor Total	4007.10	17			

The Model F-value of 7.90 implies the model is significant. There is only a 0.17% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant. In this case A, B, AB are significant model terms.

- (b) Graphically analyze the residuals. Are there any concerns about underlying assumptions or model adequacy?

The plot of residuals versus pressure shows a decreasing funnel shape indicating a non-constant variance.

- (c) Verify that if we let the low, medium and high levels of both factors in this experiment take on the levels -1, 0, and +1, then a least squares fit to a second order model for yield is

$$\hat{y} = 86.81 + 10.4x_1 + 8.42x_2 - 7.17x_1^2 - 7.86x_2^2 - 7.69x_1x_2$$

The coefficients can be found in the following table of computer output.

Design Expert Output

Final Equation in Terms of Coded Factors:

Yield =	+86.81
	+8.42 * A
	+10.40 * B
	-7.84 * A ²
	-7.17 * B ²
	-7.69 * A * B

- (d) Confirm that the model in part (c) can be written in terms of the natural variables temperature (T) and pressure (P) as

$$\hat{y} = -1335.63 + 18.56T + 8.59P - 0.072T^2 - 0.0196P^2 - 0.0384TP$$

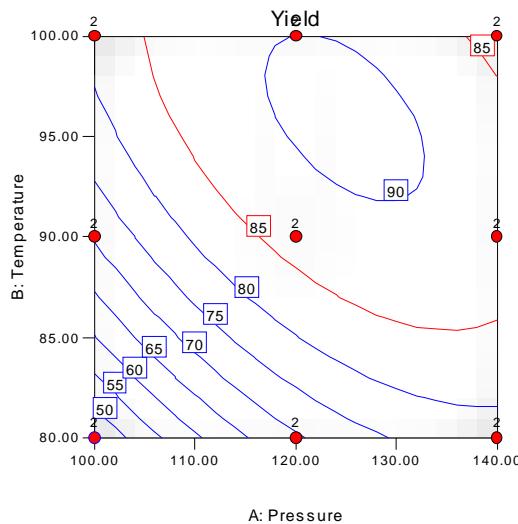

The coefficients can be found in the following table of computer output.

Design Expert Output

Final Equation in Terms of Actual Factors:

Yield	=
-1335.62500	
+8.58737	* Pressure
+18.55850	* Temperature
-0.019612	* Pressure ²
-0.071700	* Temperature ²
-0.038437	* Pressure * Temperature

- (e) Construct a contour plot for yield as a function of pressure and temperature. Based on the examination of this plot, where would you recommend running the process.

Run the process in the oval region indicated by the yield of 90.

9-7

- (a) Confound a 3^3 design in three blocks using the ABC^2 component of the three-factor interaction. Compare your results with the design in Figure 9-7.

$$L = X_1 + X_2 + 2X_3$$

Block 1	Block 2	Block 3
000	100	200
112	212	012
210	010	110
120	220	020

022	122	222
202	002	102
221	021	121
101	201	001
011	111	211

The new design is a 180° rotation around the Factor B axis.

- (b) Confound a 3^3 design in three blocks using the AB^2C component of the three-factor interaction. Compare your results with the design in Figure 9-7.

$$L = X_1 + 2X_2 + X_3$$

Block 1	Block 2	Block 3
000	210	112
022	202	120
011	221	101
212	100	010
220	122	002
201	111	021
110	012	200
102	020	222
121	001	211

The new design is a 180° rotation around the Factor C axis.

- (c) Confound a 3^3 design three blocks using the ABC component of the three-factor interaction. Compare your results with the design in Figure 9-7.

$$L = X_1 + X_2 + X_3$$

Block 1	Block 2	Block 3
000	112	221
210	022	101
120	202	011
021	100	212
201	010	122
111	220	002
012	121	200
222	001	110
102	211	020

The new design is a 90° rotation around the Factor C axis along with switching layer 0 and layer 1 in the C axis.

- (d) After looking at the designs in parts (a), (b), and (c) and Figure 9-7, what conclusions can you draw?

All four designs are relatively the same. The only differences are rotations and swapping of layers.

9-8 Confound a 3^4 design in three blocks using the AB^2CD component of the four-factor interaction.

$$L = X_1 + 2X_2 + X_3 + X_4$$

Block 1								
0000	1100	0110	0101	2200	0220	0202	1210	1201

The Model F-value of 4.27 implies the model is significant. There is only a 4.04% chance that a "Model F-Value" this large could occur due to noise.

Values of "Prob > F" less than 0.0500 indicate model terms are significant. In this case B are significant model terms.

9-10 Outline the analysis of variance table for the 3^4 design in nine blocks. Is this a practical design?

Any experiment with 81 runs is large. Instead of having three full levels of each factor, if two levels of each factor could be used, then the overall design would have 16 runs plus some center points. This two-level design could now probably be run in 2 or 4 blocks, with center points in each block. Additional curvature effects could be determined by augmenting the experiment with the axial points of a central composite design and additional enter points. The overall design would be less than 81 runs.

9-11 Consider the data in Problem 9-3. If ABC is confounded in replicate I and ABC^2 is confounded in replicate II, perform the analysis of variance.

$L_1 = X_1 + X_2 + X_3$			$L_2 = X_1 + X_2 + 2X_3$

201 = 4.96	202 = 4.17	200 = 4.20	120 = 4.85	220 = 5.58	020 = 5.23
012 = 3.94	010 = 4.14	011 = 5.22	210 = 4.37	010 = 4.19	110 = 4.26
021 = 6.21	022 = 5.14	020 = 5.80	112 = 4.08	212 = 4.48	012 = 4.08

The sums of squares for A , B , C , AB , AC , and BC are calculated as usual. The only sums of squares presenting difficulties with calculations are the four components of the ABC interaction (ABC , ABC^2 , AB^2C , and AB^2C^2). ABC is computed using replicate I and ABC^2 is computed using replicate II. AB^2C and AB^2C^2 are computed using data from both replicates.

We will show how to calculate AB^2C and AB^2C^2 from both replicates. Form a two-way table of $A \times B$ at each level of C . Find the I(AB) and J(AB) totals for each third of the $A \times B$ table.

		A				
C	B	0	1	2	I	J
		0	6.81	7.59	7.88	26.70
0	1	8.33	8.64	8.63	27.25	27.17
	2	11.03	10.33	11.25	26.54	25.77
	0	9.20	8.96	9.35	31.41	31.25
1	1	9.92	9.80	9.92	30.97	31.29

	2	12.09	12.45	12.41	31.72	31.57
	0	7.73	8.34	8.05	26.09	26.29
2	1	8.02	8.61	9.34	27.31	26.11
	2	9.63	9.58	9.75	25.65	26.65

The I and J components for each third of the above table are used to form a new table of diagonal totals.

C	I(AB)			J(AB)		
0	2.670	27.25	26.54	27.55	27.17	25.77
1	31.41	30.97	31.72	31.25	31.29	31.57
2	26.09	27.31	25.65	26.29	26.11	26.65

$$\begin{array}{ll} \text{I Totals:} & \text{I Totals:} \\ 85.06, 85.26, 83.32 & 85.99, 85.03, 83.12 \end{array}$$

$$\begin{array}{ll} \text{J Totals:} & \text{J Totals:} \\ 85.73, 83.60, 84.31 & 83.35, 85.06, 85.23 \end{array}$$

$$\text{Now, } AB^2C^2 = I[C \times I(AB)] = \frac{(85.06)^2 + (85.26)^2 + (83.32)^2}{18} - \frac{(253.64)^2}{54} = 0.1265$$

$$\text{and, } AB^2C = J[C \times I(AB)] = \frac{(85.73)^2 + (83.60)^2 + (84.31)^2}{18} - \frac{(253.64)^2}{54} = 0.1307$$

If it were necessary, we could find ABC^2 as $ABC^2 = I[C \times J(AB)]$ and ABC as $J[C \times J(AB)]$. However, these components must be computed using the data from the appropriate replicate.

9-13 From examining Figure 9-9, what type of design would remain if after completing the first 9 runs, one of the three factors could be dropped?

A full 3^2 factorial design results.

9-14 Construct a 3_{IV}^{4-1} design with $I=ABCD$. Write out the alias structure for this design.

The 27 runs for this design are as follows:

0000	1002	2001
0012	1011	2010
0021	1020	2022
0102	1101	2100
0111	1110	2112
0120	1122	2121
0201	1200	2202
0210	1212	2211
0222	1221	2220

$$\begin{array}{llll}
 A = AB^2C^2D^2 = BCD & B = AB^2CD = ACD & C = ABC^2D = ABD & D = ABCD^2 = ABC \\
 AB = ABC^2D^2 = CD & AB^2 = AC^2D^2 = BC^2D^2 & AC = AB^2CD^2 = BD & AC^2 = AB^2D^2 = BC^2D \\
 BC = AB^2C^2D = AD & BC^2 = AB^2D = AC^2D & BD^2 = AB^2C = ACD^2 & CD^2 = ABC^2 = ABCD^2 \\
 AD^2 = AB^2C^2 = BCD^2 & & &
 \end{array}$$

9-15 Verify that the design in Problem 9-14 is a resolution IV design.

The design in Problem 9-14 is a Resolution IV design because no main effect is aliased with a component of a two-factor interaction, but some two-factor interaction components are aliased with each other.

9-16 Construct a 3^{5-2} design with $I=ABC$ and $I=CDE$. Write out the alias structure for this design. What is the resolution of this design?

The complete defining relation for this design is : $I = ABC = CDE = ABC^2DE = ABD^2E^2$

This is a resolution III design. The defining contrasts are $L_1 = X_1 + X_2 + X_3$ and $L_2 = X_3 + X_4 + X_5$.

00000	11120	20111
00012	22111	22222
00022	21021	01210
01200	02111	12000
02100	01222	20120
10202	12012	11111
20101	02120	22201
11102	10210	21012
21200	12021	10222

To find the alias of any effect, multiply the effect by I and I^2 . For example, the alias of A is:

$$A = AB^2C^2 = ACDE = AB^2CDE = AB^2DE = BC = AC^2D^2E^2 = BC^2DE = BD^2E^2$$

9-17 Construct a 3^{9-6} design, and verify that is a resolution III design.

Use the generators $I = AC^2D^2$, $I = AB^2C^2E$, $I = BC^2F^2$, $I = AB^2CG$, $I = ABCH^2$, and $I = ABJ^2$

000000000	021201102	102211001
022110012	212012020	001212210
011220021	100120211	211100110
221111221	122200220	020022222
210221200	010011111	222020101

112222112	002121120	121021010
101002121	111010202	110101022
120112100	220202011	012102201

To find the alias of any effect, multiply the effect by I and I^2 . For example, the alias of C is:

$C = C(BC^2F^2) = BF^2$, At least one main effect is aliased with a component of a two-factor interaction.

9-18 Construct a 4×2^3 design confounded in two blocks of 16 observations each. Outline the analysis of variance for this design.

Design is a 4×2^3 , with ABC at two levels, and Z at 4 levels. Represent Z with two pseudo-factors D and E as follows:

Factor	Pseudo-	Factors
Z	D	E
Z_1	0	$0 = (1)$
Z_2	1	$0 = d$
Z_3	0	$1 = e$
Z_4	1	$1 = de$

The 4×2^3 is now a 2^5 in the factors A, B, C, D and E . Confound $ABCDE$ with blocks. We have given both the letter notation and the digital notation for the treatment combinations.

9-19 Outline the analysis of variance table for a 2^23^2 factorial design. Discuss how this design may be confounded in blocks.

Suppose we have n replicates of a 2^23^2 factorial design. A and B are at 2 levels, and C and D are at 3 levels.

Source	DF	Components for Confounding
A	1	A
B	1	B
C	2	C
D	2	D
AB	1	AB
AC	2	AC
AD	2	AD

BC	2	BD
BD	2	CD, CD^2
CD	4	ABC
ABC	2	ABD
ABD	2	ACD, ACD^2
ACD	4	BCD, BCD^2
BCD	4	$ABCD, ABCD^2$
$ABCD$	4	
Error	$36(n-1)$	
Total	$36n-1$	

Confounding in this series of designs is discussed extensively by Margolin (1967). The possibilities for a single replicate of the 2^23^2 design are:

2 blocks of 18 observations	6 blocks of 6 observations
3 blocks of 12 observations	9 blocks of 4 observations
4 blocks of 9 observations	

For example, one component of the four-factor interaction, say $ABCD^2$, could be selected to confound the design in 3 blocks for 12 observations each, while to confound the design in 2 blocks of 18 observations 3 each we would select the AB interaction. Cochran and Cox (1957) and Anderson and McLean (1974) discuss confounding in these designs.

9-20 Starting with a 16-run 2^4 design, show how two three-level factors can be incorporated in this experiment. How many two-level factors can be included if we want some information on two-factor interactions?

Use column A and B for one three-level factor and columns C and D for the other. Use the AC and BD columns for the two, two-level factors. The design will be of resolution V.

9-21 Starting with a 16-run 2^4 design, show how one three-level factor and three two-level factors can be accommodated and still allow the estimation of two-factor interactions.

Use columns A and B for the three-level factor, and columns C and D and $ABCD$ for the three two-level factors. This design will be of resolution V.

9-22 In Problem 9-26, you met Harry and Judy Peterson-Nedry, two friends of the author who have a winery and vineyard in Newberg, Oregon. That problem described the application of two-level fractional factorial designs to their 1985 Pinor Noir product. In 1987, they wanted to conduct another Pinot Noir experiment. The variables for this experiment were

<u>Variable</u>	<u>Levels</u>
Clone of Pinot Noir	Wadenswil, Pommard
Berry Size	Small, Large
Fermentation temperature	80F, 85F, 90/80F, 90F
Whole Berry	None, 10%
Maceration Time	10 days, 21 days
Yeast Type	Assmanhau, Champagne
Oak Type	Troncais, Allier

Harry and Judy decided to use a 16-run two-level fractional factorial design, treating the four levels of fermentation temperature as two two-level variables. As in Problem 8-26, they used the rankings from a taste-test panel as the response variable. The design and the resulting average ranks are shown below:

Berry	Ferm.	Whole	Macer.	Yeast	Oak	Average
-------	-------	-------	--------	-------	-----	---------

Run	Clone	Size	Temp.	Berry	Time	Type	Type	Rank
1	-	-	-	-	-	-	-	4
2	+	-	-	-	+	+	+	10
3	-	+	-	+	-	+	+	6
4	+	+	-	+	+	-	-	9
5	-	-	+	-	+	+	-	11
6	+	-	+	-	-	-	+	1
7	-	+	+	-	+	-	+	15
8	+	+	+	-	-	+	-	5
9	-	-	-	+	+	-	+	12
10	+	-	-	+	-	+	-	2
11	-	+	-	+	+	+	-	16
12	+	+	-	+	-	-	+	3
13	-	-	+	+	-	+	+	8
14	+	-	+	+	-	-	-	14
15	-	+	+	+	-	-	-	7
16	+	+	+	+	+	+	+	13

(a) Describe the aliasing in this design.

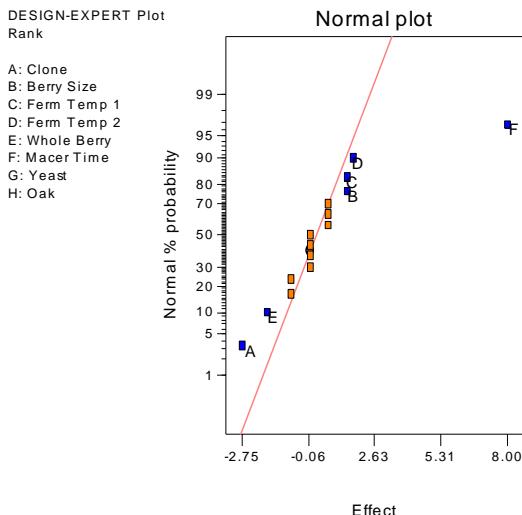

The design is a resolution IV design such that the main effects are aliased with three factor interactions.

- (c) What comparisons can you make between this experiment and the 1985 Pinot Noir experiment from Problem 8-26?

The experiment from Problem 8-26 indicates that yeast, barrel, whole cluster and the clone x yeast interactions were significant. This experiment indicates that maceration time, whole berry, clone and fermentation temperature are significant.

9-23 An article by W.D. Baten in the 1956 volume of *Industrial Quality Control* described an experiment to study the effect of three factors on the lengths of steel bars. Each bar was subjected to one of two heat treatment processes, and was cut on one of four machines at one of three times during the day (8 am, 11 am, or 3 pm). The coded length data are shown below

- (a) Analyze the data from this experiment assuming that the four observations in each cell are replicates.

The Machine effect (C) is significant, the Heat Treat Process (B) is also significant, while the Time of Day (A) is not significant. None of the interactions are significant.

- (b) Analyze the residuals from this experiment. Is there any indication that there is an outlier in one cell? If you find an outlier, remove it and repeat the analysis from part (a). What are your conclusions?

Standard Order 84, Time of Day at 3:00pm, Heat Treat #2, Machine #2, and length of 0, appears to be an outlier.

The following analysis was performed with the outlier described above removed. As with the original analysis, Machine is significant and Heat Treat Process is also significant, but now Time of Day, factor A, is also significant with an F -value of 3.05 (the P -value is just above 0.05).

+1.92 * C[2]
-3.08 * C[3]
    
```

The following residual plots are acceptable. Both the normality and uniformity of variance assumptions are verified.

- (d) Calculate the log variance of the observations in each cell. Analyze the average length and the log variance of the length for each of the 12 bars cut at each machine/heat treatment process combination. What conclusions can you draw?

Factor *B*, Heat Treat Process, has an affect on the log variance of the observations while Factor *A*, Time of Day, and Factor *C*, Machine, are not significant at the 5 percent level. However, *A* is significant at the 10 percent level, so Tome of Day has some effect on the variance.

The following residual plots are acceptable. Both the normality and uniformity of variance assumptions are verified.

Chapter 10

Fitting Regression Models

Solutions

10-1 The tensile strength of a paper product is related to the amount of hardwood in the pulp. Ten samples are produced in the pilot plant, and the data obtained are shown in the following table.

Strength	Percent Hardwood	Strength	Percent Hardwood
160	10	181	20
171	15	188	25
175	15	193	25
182	20	195	28
184	20	200	30

- (a) Fit a linear regression model relating strength to percent hardwood.

Minitab Output

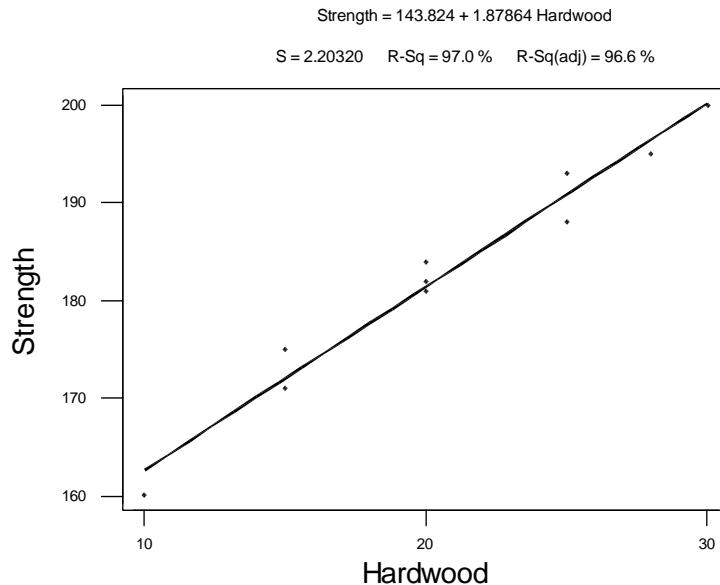

Regression Analysis: Strength versus Hardwood

The regression equation is
Strength = 144 + 1.88 Hardwood

Predictor	Coef	SE Coef	T	P
Constant	143.824	2.522	57.04	0.000
Hardwood	1.8786	0.1165	16.12	0.000

S = 2.203 R-Sq = 97.0% R-Sq(adj) = 96.6%
PRESS = 66.2665 R-Sq(pred) = 94.91%

Regression Plot

- (b) Test the model in part (a) for significance of regression.

Octane	1	1132.56
Compress	1	947.83

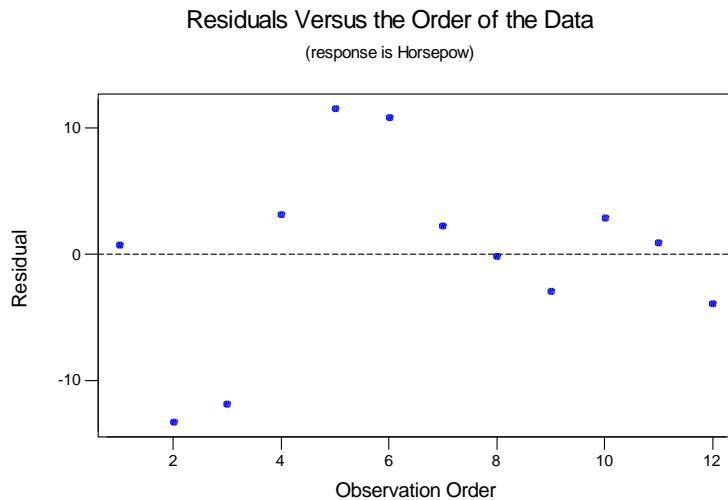

Lack of fit test
 Possible interactions with variable Octane (P-Value = 0.028)
 Possible lack of fit at outer X-values (P-Value = 0.000)
 Overall lack of fit test is significant at P = 0.000

(c) Based on *t* tests, do you need all three regressor variables in the model?

Yes, all of the regressor variables are important.

10-8 Analyze the residuals from the regression model in Problem 10-7. Comment on model adequacy.

The normal probability plot is satisfactory, as is the plot of residuals versus run order (assuming that observation order is run order). The plot of residuals versus predicted response exhibits a slight “bow” shape. This could be an indication of lack of fit. It might be useful to consider adding some interaction terms to the model.

- 10-9** The yield of a chemical process is related to the concentration of the reactant and the operating temperature. An experiment has been conducted with the following results.

Yield	Concentration	Temperature
81	1.00	150
89	1.00	180
83	2.00	150
91	2.00	180
79	1.00	150
87	1.00	180
84	2.00	150
90	2.00	180

- (a) Suppose we wish to fit a main effects model to this data. Set up the $\mathbf{X}'\mathbf{X}$ matrix using the data exactly as it appears in the table.

$$\begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1.00 & 1.00 & 2.00 & 2.00 & 1.00 & 1.00 & 2.00 & 2.00 \\ 150 & 180 & 150 & 180 & 150 & 180 & 150 & 180 \end{bmatrix} \begin{bmatrix} 1 & 1.00 & 150 \\ 1 & 1.00 & 180 \\ 1 & 2.00 & 150 \\ 1 & 2.00 & 180 \\ 1 & 1.00 & 150 \\ 1 & 1.00 & 180 \\ 1 & 2.00 & 150 \\ 1 & 2.00 & 180 \end{bmatrix} = \begin{bmatrix} 8 & 12 & 1320 \\ 12 & 20 & 1980 \\ 1320 & 1980 & 219600 \end{bmatrix}$$

- (b) Is the matrix you obtained in part (a) diagonal? Discuss your response.

The $\mathbf{X}'\mathbf{X}$ is not diagonal, even though an orthogonal design has been used. The reason is that we have worked with the natural factor levels, not the orthogonally coded variables.

- (c) Suppose we write our model in terms of the “usual” coded variables

$$x_1 = \frac{\text{Conc} - 1.5}{0.5}, x_2 = \frac{\text{Temp} - 165}{15}$$

Set up the $\mathbf{X}'\mathbf{X}$ matrix for the model in terms of these coded variables. Is this matrix diagonal? Discuss your response.

$$\begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ -1 & -1 & 1 & 1 & -1 & -1 & 1 & 1 \\ -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 & -1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \\ 1 & 1 & 1 \\ 1 & -1 & -1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \\ 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 8 & 0 & 0 \\ 0 & 8 & 0 \\ 0 & 0 & 8 \end{bmatrix}$$

The $\mathbf{X}'\mathbf{X}$ matrix is diagonal because we have used the orthogonally coded variables.

- (d) Define a new set of coded variables

$$x_1 = \frac{\text{Conc} - 1.0}{1.0}, x_2 = \frac{\text{Temp} - 150}{30}$$

Set up the $\mathbf{X}'\mathbf{X}$ matrix for the model in terms of this set of coded variables. Is this matrix diagonal? Discuss your response.

$$\begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 8 & 4 & 4 \\ 4 & 4 & 2 \\ 4 & 2 & 4 \end{bmatrix}$$

The $\mathbf{X}'\mathbf{X}$ is not diagonal, even though an orthogonal design has been used. The reason is that we have not used orthogonally coded variables.

- (e) Summarize what you have learned from this problem about coding the variables.

If the design is orthogonal, use the orthogonal coding. This not only makes the analysis somewhat easier, but it also results in model coefficients that are easier to interpret because they are both dimensionless and uncorrelated.

10-10 Consider the 2^4 factorial experiment in Example 6-2. Suppose that the last observation is missing. Reanalyze the data and draw conclusions. How do these conclusions compare with those from the original example?

The regression analysis with the one data point missing indicates that the same effects are important.

Minitab Output

Regression Analysis: Rate versus A, B, C, D, AB, AC, AD, BC, BD, CD

10-13

- (a) Consider the quadratic regression model from Problem 10-12. Compute t statistics for each model parameter and comment on the conclusions that follow from the quantities.

Minitab Output

Predictor	Coef	SE Coef	T	P	VIF
Constant	24.41	26.59	0.92	0.394	
x1	-38.03	40.45	-0.94	0.383	89.6
x2	0.72	11.69	0.06	0.953	52.1
x1^2	34.98	21.56	1.62	0.156	103.9
x2^2	11.066	3.158	3.50	0.013	104.7
x1x2	-9.986	8.742	-1.14	0.297	105.1

x_2^2 is the only model parameter that is statistically significant with a t -value of 3.50. A logical model might also include x_2 to preserve model hierarchy.

- (b) Use the extra sum of squares method to evaluate the value of the quadratic terms, x_1^2 , x_2^2 and x_1x_2 to the model.

The extra sum of squares due to β_2 is

$$SS_R(\boldsymbol{\beta}_2 | \boldsymbol{\beta}_0, \boldsymbol{\beta}_1) = SS_R(\boldsymbol{\beta}_0, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2) - SS_R(\boldsymbol{\beta}_0, \boldsymbol{\beta}_1) = SS_R(\boldsymbol{\beta}_1, \boldsymbol{\beta}_2 | \boldsymbol{\beta}_0) - SS_R(\boldsymbol{\beta}_1 | \boldsymbol{\beta}_0)$$

$SS_R(\boldsymbol{\beta}_1, \boldsymbol{\beta}_2 | \boldsymbol{\beta}_0)$ sum of squares of regression for the model in Problem 10-12 = 35092.6

$$SS_R(\boldsymbol{\beta}_1 | \boldsymbol{\beta}_0) = 34502.3$$

$$SS_R(\boldsymbol{\beta}_2 | \boldsymbol{\beta}_0, \boldsymbol{\beta}_1) = 35092.6 - 34502.3 = 590.3$$

$$F_0 = \frac{SS_R(\boldsymbol{\beta}_2 | \boldsymbol{\beta}_0, \boldsymbol{\beta}_1) / 3}{MS_E} = \frac{590.3 / 3}{36.511} = 5.3892$$

Since $F_{0.05,3,6} = 4.76$, then the addition of the quadratic terms to the model is significant. The P-values indicate that it's probably the term x_2^2 that is responsible for this.

10-14 Relationship between analysis of variance and regression. Any analysis of variance model can be expressed in terms of the general linear model $\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\varepsilon}$, where the \mathbf{X} matrix consists of zeros and ones. Show that the single-factor model $y_{ij} = \mu + \tau_i + \varepsilon_{ij}$, $i=1,2,3$, $j=1,2,3,4$ can be written in general linear model form. Then

- (a) Write the normal equations $(\mathbf{X}'\mathbf{X})\hat{\boldsymbol{\beta}} = \mathbf{X}'\mathbf{y}$ and compare them with the normal equations found for the model in Chapter 3.

The normal equations are $(\mathbf{X}'\mathbf{X})\hat{\boldsymbol{\beta}} = \mathbf{X}'\mathbf{y}$

$$\begin{bmatrix} 12 & 4 & 4 & 4 \\ 4 & 4 & 0 & 0 \\ 4 & 0 & 4 & 0 \\ 4 & 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} \hat{\mu} \\ \hat{\tau}_1 \\ \hat{\tau}_2 \\ \hat{\tau}_3 \end{bmatrix} = \begin{bmatrix} y_{..} \\ y_{1..} \\ y_{2..} \\ y_{3..} \end{bmatrix}$$

which are in agreement with the results of Chapter 3.

- (b) Find the rank of $\mathbf{X}'\mathbf{X}$. Can $(\mathbf{X}'\mathbf{X})^{-1}$ be obtained?

$\mathbf{X}'\mathbf{X}$ is a 4×4 matrix of rank 3, because the last three columns add to the first column. Thus $(\mathbf{X}'\mathbf{X})^{-1}$ does not exist.

- (c) Suppose the first normal equation is deleted and the restriction $\sum_{i=1}^3 n\hat{\tau}_i = 0$ is added. Can the resulting system of equations be solved? If so, find the solution. Find the regression sum of squares $\hat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{y}$, and compare it to the treatment sum of squares in the single-factor model.

Imposing $\sum_{i=1}^3 n\hat{\tau}_i = 0$ yields the normal equations

$$\begin{bmatrix} 0 & 4 & 4 & 4 \\ 4 & 4 & 0 & 0 \\ 4 & 0 & 4 & 0 \\ 4 & 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} \hat{\mu} \\ \hat{\tau}_1 \\ \hat{\tau}_2 \\ \hat{\tau}_3 \end{bmatrix} = \begin{bmatrix} y_{..} \\ y_{1..} \\ y_{2..} \\ y_{3..} \end{bmatrix}$$

The solution to this set of equations is

$$\begin{aligned} \hat{\mu} &= \frac{y_{..}}{12} = \bar{y}_{..} \\ \hat{\tau}_i &= \bar{y}_{i..} - \bar{y}_{..} \end{aligned}$$

This solution was found by solving the last three equations for $\hat{\tau}_i$, yielding $\hat{\tau}_i = \bar{y}_{i..} - \hat{\mu}$, and then substituting in the first equation to find $\hat{\mu} = \bar{y}_{..}$.

The regression sum of squares is

$$SS_R(\boldsymbol{\beta}) = \hat{\boldsymbol{\beta}}' \mathbf{X}' \mathbf{y} = \bar{y}_{..} y_{..} + \sum_{i=1}^a (\bar{y}_{i..} - \bar{y}_{..})^2 = \frac{y_{..}^2}{an} + \sum_{i=1}^a \frac{\bar{y}_{i..}^2}{n} - \frac{y_{..}^2}{an} = \sum_{i=1}^a \frac{\bar{y}_{i..}^2}{n}$$

with a degrees of freedom. This is the same result found in Chapter 3. For more discussion of the relationship between analysis of variance and regression, see Montgomery and Peck (1992).

10-15 Suppose that we are fitting a straight line and we desire to make the variance of as small as possible. Restricting ourselves to an even number of experimental points, where should we place these points so as to minimize $V(\hat{\beta}_1)$? (Note: Use the design called for in this exercise with great caution because, even though it minimized $V(\hat{\beta}_1)$, it has some undesirable properties; for example, see Myers and Montgomery (1995). Only if you are *very sure* the true functional relationship is linear should you consider using this design.

Since $V(\hat{\beta}_1) = \frac{\sigma^2}{S_{xx}}$, we may minimize $V(\hat{\beta}_1)$ by making S_{xx} as large as possible. S_{xx} is maximized by spreading out the x_j 's as much as possible. The experimenter usually has a “region of interest” for x . If n is even, $n/2$ of the observations should be run at each end of the “region of interest”. If n is odd, then run one of the observations in the center of the region and the remaining $(n-1)/2$ at either end.

10-16 Weighted least squares. Suppose that we are fitting the straight line $y = \beta_0 + \beta_1 x + \varepsilon$, but the variance of the y 's now depends on the level of x ; that is,

$$V(y|x_i) = \sigma^2 = \frac{\sigma^2}{w_i}, i = 1, 2, \dots, n$$

where the w_i are known constants, often called weights. Show that if we choose estimates of the regression coefficients to minimize the weighted sum of squared errors given by $\sum_{i=1}^n w_i (y_i - \beta_0 + \beta_1 x_i)^2$, the resulting least squares normal equations are

$$\begin{aligned}\hat{\beta}_0 \sum_{i=1}^n w_i + \hat{\beta}_1 \sum_{i=1}^n w_i x_i &= \sum_{i=1}^n w_i y_i \\ \hat{\beta}_0 \sum_{i=1}^n w_i x_i + \hat{\beta}_1 \sum_{i=1}^n w_i x_i^2 &= \sum_{i=1}^n w_i x_i y_i\end{aligned}$$

The least squares normal equations are found:

$$L = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_1)^2 w_i$$

$$\frac{\partial L}{\partial \beta_0} = -2 \sum_{i=1}^n (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_1) w_i = 0$$

$$\frac{\partial L}{\partial \beta_1} = -2 \sum_{i=1}^n (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_1) x_1 w_i = 0$$

which simplify to

$$\hat{\beta}_0 \sum_{i=1}^n w_i + \hat{\beta}_1 \sum_{i=1}^n x_1 w_i = \sum_{i=1}^n w_i y_i$$

$$\hat{\beta}_0 \sum_{i=1}^n x_1 w_i + \hat{\beta}_1 \sum_{i=1}^n x_1^2 w_i = \sum_{i=1}^n w_i x_1 y_i$$

10-17 Consider the 2^{4-1}_{IV} design discussed in Example 10-5.

- (a) Suppose you elect to augment the design with the single run selected in that example. Find the variances and covariances of the regression coefficients in the model (ignoring blocks):

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_4 x_4 + \beta_{12} x_1 x_2 + \beta_{34} x_3 x_4 + \varepsilon$$

$$\mathbf{X}' \mathbf{X} = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 \\ -1 & -1 & 1 & 1 & -1 & -1 & 1 & -1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & -1 \\ -1 & 1 & 1 & -1 & 1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 \\ 1 & -1 & 1 & 1 & -1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 & -1 & -1 & -1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 & 1 & -1 & -1 & -1 \\ 1 & -1 & 1 & -1 & 1 & -1 & -1 & -1 \\ 1 & 1 & 1 & -1 & -1 & 1 & 1 & 1 \\ 1 & -1 & -1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & 1 & -1 & -1 & -1 & -1 \\ 1 & -1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 9 & -1 & -1 & -1 & -1 & 1 & 1 & -1 \\ -1 & 9 & 1 & 1 & -1 & -1 & -1 & 1 \\ -1 & 1 & 9 & 1 & -1 & -1 & 1 & 1 \\ -1 & 1 & 1 & 9 & -1 & -1 & 1 & 1 \\ -1 & 1 & 1 & -1 & -1 & 9 & 1 & -1 \\ 1 & -1 & -1 & -1 & -1 & 9 & 1 & -1 \\ 1 & -1 & -1 & -1 & 1 & 9 & 7 & 1 \\ -1 & 1 & 1 & 1 & -1 & 7 & 9 & 1 \end{bmatrix}$$

$$(\mathbf{X}' \mathbf{X})^{-1} = \begin{bmatrix} 0.125 & 0 & 0 & 0 & 0 & -0.0625 & 0.0625 \\ 0 & 0.125 & 0 & 0 & 0 & 0.0625 & -0.0625 \\ 0 & 0 & 0.125 & 0 & 0 & 0.0625 & -0.0625 \\ 0 & 0 & 0 & 0.125 & 0 & 0.0625 & -0.0625 \\ 0 & 0 & 0 & 0 & 0.125 & -0.0625 & 0.0625 \\ -0.0625 & 0.0625 & 0.0625 & 0.0625 & 0.0625 & 0.4375 & -0.375 \\ 0.0625 & -0.0625 & -0.0625 & -0.0625 & 0.0625 & -0.375 & 0.4375 \end{bmatrix}$$

- (b) Are there any other runs in the alternate fraction that would de-alias AB from CD ?

Any other run from the alternate fraction will de-alias AB from CD .

- (c) Suppose you augment the design with four runs suggested in Example 10-5. Find the variance and the covariances of the regression coefficients (ignoring blocks) for the model in part (a).

Choose 4 runs that are one of the quarter fractions not used in the principal half fraction.

$$\mathbf{X}'\mathbf{X} = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ -1 & -1 & 1 & 1 & -1 & -1 & 1 & 1 & 1 & -1 & -1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & -1 & -1 & 1 & 1 \\ -1 & 1 & 1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & -1 & 1 & 1 & 1 & -1 & -1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & 1 & 1 & -1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix}$$

$$\mathbf{X}'\mathbf{X} = \begin{bmatrix} 12 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 12 & 0 & 0 & 4 & 4 & 0 \\ 0 & 0 & 12 & -4 & 0 & 0 & 0 \\ 0 & 0 & -4 & 12 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 & 12 & 4 & 0 \\ 0 & 4 & 0 & 0 & 4 & 12 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 12 \end{bmatrix}$$

$$(\mathbf{X}'\mathbf{X})^{-1} = \begin{bmatrix} 0.0833 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0.1071 & 0 & 0 & -0.0179 & -0.0536 & 0.0357 \\ 0 & 0 & 0.0938 & 0.0313 & 0 & 0 & 0 \\ 0 & 0 & 0.0313 & 0.0938 & 0 & 0 & 0 \\ 0 & -0.0179 & 0 & 0 & 0.1071 & -0.0536 & 0.0357 \\ 0 & -0.0536 & 0 & 0 & -0.0536 & 0.2142 & -0.1429 \\ 0 & 0.0357 & 0 & 0 & 0.0357 & -0.1429 & 0.1785 \end{bmatrix}$$

(d) Considering parts (a) and (c), which augmentation strategy would you prefer and why?

If you only have the resources to run one more run, then choose the one-run augmentation. But if resources are not scarce, then augment the design in multiples of two runs, to keep the design orthogonal. Using four runs results in smaller variances of the regression coefficients and a simpler covariance structure.

10-18 Consider the 2^{7-4}_{III} . Suppose after running the experiment, the largest observed effects are $A + BD$, $B + AD$, and $D + AB$. You wish to augment the original design with a group of four runs to de-alias these effects.

(a) Which four runs would you make?

Take the first four runs of the original experiment and change the sign on A .

Chapter 11

Response Surface Methods and Designs

Solutions

11-1 A chemical plant produces oxygen by liquefying air and separating it into its component gases by fractional distillation. The purity of the oxygen is a function of the main condenser temperature and the pressure ratio between the upper and lower columns. Current operating conditions are temperature (ξ_1) = -220°C and pressure ratio (ξ_2) = 1.2. Using the following data find the path of steepest ascent.

Temperature (x_1)	Pressure Ratio (x_2)	Purity
-225	1.1	82.8
-225	1.3	83.5
-215	1.1	84.7
-215	1.3	85.0
-220	1.2	84.1
-220	1.2	84.5
-220	1.2	83.9
-220	1.2	84.3

Final Equation in Terms of Coded Factors:

$$\begin{aligned} \text{Purity} = & \\ & +84.00 \\ & +0.85 * A \\ & +0.25 * B \end{aligned}$$

Final Equation in Terms of Actual Factors:

$$\begin{aligned} \text{Purity} = & \\ & +118.40000 \\ & +0.17000 * \text{Temperature} \end{aligned}$$

+2.50000 * Pressure Ratio

From the computer output use the model $\hat{y} = 84 + 0.85x_1 + 0.25x_2$ as the equation for steepest ascent.

Suppose we use a one degree change in temperature as the basic step size. Thus, the path of steepest ascent passes through the point $(x_1=0, x_2=0)$ and has a slope $0.25/0.85$. In the coded variables, one degree of temperature is equivalent to a step of $\Delta x_1 = 1/5=0.2$. Thus, $\Delta x_2 = (0.25/0.85)0.2=0.059$. The path of steepest ascent is:

	Coded Variables x_1	Natural Variables ξ_1		Coded Variables x_2	Natural Variables ξ_2

The equation used to compute the path of steepest ascent is $\hat{y} = 659 + 9.25x_1 + 13.25x_3 + 7.50x_4$. Notice that even though the model contains interaction, it is relatively common practice to ignore the interactions in computing the path of steepest ascent. This means that the path constructed is only an approximation to the path that would have been obtained if the interactions were considered, but it's usually close enough to give satisfactory results.

It is helpful to give a general method for finding the path of steepest ascent. Suppose we have a first-order model in k variables, say

$$\hat{y} = \hat{\beta}_0 + \sum_{i=1}^k \hat{\beta}_i x_i$$

The path of steepest ascent passes through the origin, $\mathbf{x}=\mathbf{0}$, and through the point on a hypersphere of radius, R where \hat{y} is a maximum. Thus, the x 's must satisfy the constraint

$$\sum_{i=1}^k x_i^2 = R^2$$

To find the set of x 's that maximize \hat{y} subject to this constraint, we maximize

$$L = \hat{\beta}_0 + \sum_{i=1}^k \hat{\beta}_i x_i - \lambda \left[\sum_{i=1}^k x_i^2 - R^2 \right]$$

where λ is a LaGrange multiplier. From $\partial L / \partial x_i = \partial L / \partial \lambda = 0$, we find

$$x_i = \frac{\hat{\beta}_i}{2\lambda}$$

It is customary to specify a basic step size in one of the variables, say Δx_j , and then calculate 2λ as $2\lambda = \hat{\beta}_j / \Delta x_j$. Then this value of 2λ can be used to generate the remaining coordinates of a point on the path of steepest ascent.

We demonstrate using the data from this problem. Suppose that we use -10 units in ξ_1 as the basic step size. Note that a decrease in ξ_1 is called for, because we are looking for a path of steepest decent. Now -10 units in ξ_1 is equal to $-10/20 = -0.5$ units change in x_1 .

Thus, $2\lambda = \hat{\beta}_1 / \Delta x_1 = 9.25/(-0.5) = -18.50$

Consequently,

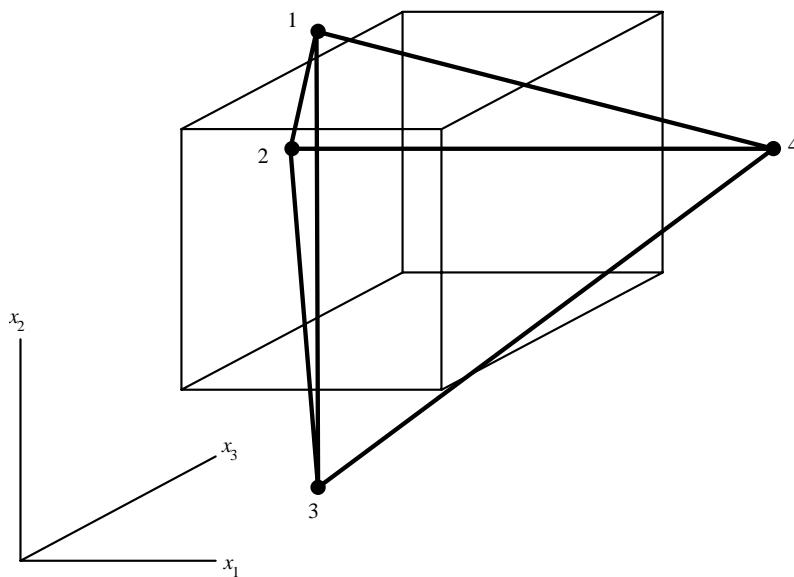

$$\begin{aligned}\Delta x_3 &= \frac{\hat{\beta}_3}{2\lambda} = \frac{13.25}{-18.50} = -0.716 \\ \Delta x_4 &= \frac{\hat{\beta}_4}{2\lambda} = \frac{7.50}{-18.50} = -0.705\end{aligned}$$

are the remaining coordinates of points along the path of steepest decent, in terms of the coded variables. The path of steepest decent is shown below:

	Coded	Variables			Natural	Variables		
	x_1	x_2	x_3	x_4	ξ_1	ξ_2	ξ_3	ξ_4
Origin	0	0	0	0	120	35	275	60
Δ	-0.50	0	-0.716	-0.405	-10	0	-17.91	-8.11
Origin + Δ	-0.50	0	-0.716	-0.405	110	35	257.09	51.89
Origin + 2 Δ	-1.00	0	-1.432	-0.810	100	35	239.18	43.78

11-3 Verify that the following design is a simplex. Fit the first-order model and find the path of steepest ascent.

Position	x_1	x_2	x_3	y
1	0	$\sqrt{2}$	-1	18.5
2	$-\sqrt{2}$	0	1	19.8
3	0	$-\sqrt{2}$	-1	17.4
4	$\sqrt{2}$	0	1	22.5

The graphical representation of the design identifies a tetrahedron; therefore, the design is a simplex.

Design Expert Output

ANOVA for Selected Factorial Model					
Analysis of variance table [Partial sum of squares]					
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F
Model	14.49	3	4.83		
A	3.64	1	3.64		
B	0.61	1	0.61		
C	10.24	1	10.24		
Pure Error	0.000	0			
Cor Total	14.49	3			
Std. Dev.			R-Squared	1.0000	
Mean	19.55		Adj R-Squared		
C.V.			Pred R-Squared	N/A	
PRESS	N/A		Adeq Precision	0.000	
Case(s) with leverage of 1.0000: Pred R-Squared and PRESS statistic not defined					
Factor	Coefficient Estimate	DF	Standard Error	95% CI Low	95% CI High
Intercept	19.55	1			
A-x1	1.35	1			1.00
B-x2	0.55	1			1.00
C-x3	1.60	1			1.00
Final Equation in Terms of Coded Factors:					
$\begin{aligned} y = & \\ & +19.55 \\ & +1.35 * A \\ & +0.55 * B \\ & +1.60 * C \end{aligned}$					
Final Equation in Terms of Actual Factors:					
$\begin{aligned} y = & \\ & +19.55000 \\ & +0.95459 * x_1 \\ & +0.38891 * x_2 \\ & +1.60000 * x_3 \end{aligned}$					

The first order model is $\hat{y} = 19.55 + 1.35x_1 + 0.55x_2 + 1.60x_3$.

To find the path of steepest ascent, let the basic step size be $\Delta x_3 = 1$. Then using the results obtained in the previous problem, we obtain

$$\Delta x_3 = \frac{\hat{\beta}_3}{2\lambda} \text{ or } 1.0 = \frac{1.60}{2\lambda}$$

which yields $2\lambda = 1.60$. Then the coordinates of points on the path of steepest ascent are defined by

$$\begin{aligned}\Delta x_1 &= \frac{\hat{\beta}_1}{2\lambda} = \frac{0.96}{1.60} = 0.60 \\ \Delta x_2 &= \frac{\hat{\beta}_2}{2\lambda} = \frac{0.24}{1.60} = 0.24\end{aligned}$$

Therefore, in the coded variables we have:

	Coded	Variables	
	x_1	x_2	x_3
Origin	0	0	0
Δ	0.60	0.24	1.00
Origin + Δ	0.60	0.24	1.00
Origin + 2 Δ	1.20	0.48	2.00

11-4 For the first-order model $\hat{y} = 60 + 1.5x_1 - 0.8x_2 + 2.0x_3$ find the path of steepest ascent. The variables are coded as $-1 \leq x_i \leq 1$.

Let the basic step size be $\Delta x_3 = 1$. $\Delta x_3 = \frac{\hat{\beta}_3}{2\lambda}$ or $1.0 = \frac{2.0}{2\lambda}$. Then $2\lambda = 2.0$

$$\begin{aligned}\Delta x_1 &= \frac{\hat{\beta}_1}{2\lambda} = \frac{1.50}{2.0} = 0.75 \\ \Delta x_2 &= \frac{\hat{\beta}_2}{2\lambda} = \frac{-0.8}{2.0} = -0.40\end{aligned}$$

Therefore, in the coded variables we have

	Coded	Variables	
	x_1	x_2	x_3
Origin	0	0	0
Δ	0.75	-0.40	1.00
Origin + Δ	0.75	-0.40	1.00
Origin + 2 Δ	1.50	-0.80	2.00

11-5 The region of experimentation for three factors are time ($40 \leq T_1 \leq 80$ min), temperature ($200 \leq T_2 \leq 300$ °C), and pressure ($20 \leq P \leq 50$ psig). A first-order model in coded variables has been fit to yield data from a 2^3 design. The model is

$$\hat{y} = 30 + 5x_1 + 2.5x_2 + 3.5x_3$$

Is the point $T_1 = 85$, $T_2 = 325$, $P=60$ on the path of steepest ascent?

The coded variables are found with the following:

$$x_1 = \frac{T_1 - 60}{20} \quad x_2 = \frac{T_2 - 250}{50} \quad x_3 = \frac{P - 35}{15}$$

$$\Delta T_1 = 5 \quad \Delta x_1 = \frac{5}{20} = 0.25$$

$$\Delta x_1 = \frac{\hat{\beta}_1}{2\lambda} \text{ or } 0.25 = \frac{20}{2\lambda} \quad 2\lambda = 20$$

$$\Delta x_2 = \frac{\hat{\beta}_2}{2\lambda} = \frac{2.5}{20} = 0.125$$

$$\Delta x_3 = \frac{\hat{\beta}_3}{2\lambda} = \frac{3.5}{20} = 0.175$$

	Coded x_1	Variables x_2	Natural x_3	Natural T_1	Variables T_2	P
Origin	0	0	0	60	250	35
Δ	0.25	0.125	0.175	5	6.25	2.625
Origin + Δ	0.25	0.125	0.175	65	256.25	37.625
Origin + 5 Δ	1.25	0.625	0.875	85	281.25	48.125

The point $T_1=85$, $T_2=325$, and $P=60$ is not on the path of steepest ascent.

11-6 The region of experimentation for two factors are temperature ($100 \leq T \leq 300$ ° F) and catalyst feed rate ($10 \leq C \leq 30$ lb/h). A first order model in the usual ± 1 coded variables has been fit to a molecular weight response, yielding the following model.

$$\hat{y} = 2000 + 125x_1 + 40x_2$$

(a) Find the path of steepest ascent.

$$x_1 = \frac{T - 200}{100} \quad x_2 = \frac{C - 20}{10}$$

$$\Delta T = 100 \quad \Delta x_1 = \frac{100}{100} = 1$$

$$\Delta x_1 = \frac{\hat{\beta}_1}{2\lambda} \text{ or } 1 = \frac{125}{2\lambda} \quad 2\lambda = 125$$

$$\Delta x_2 = \frac{\hat{\beta}_2}{2\lambda} = \frac{40}{125} = 0.32$$

	Coded x_1	Variables x_2	Natural T	Variables C
Origin	0	0	200	20
Δ	1	0.32	100	3.2

Origin + Δ	1	0.32	300	23.2
Origin + 5 Δ	5	1.60	700	36.0

- (a) It is desired to move to a region where molecular weights are above 2500. Based on the information you have from the experiment, in this region, about how many steps along the path of steepest ascent might be required to move to the region of interest?

$$\Delta \hat{y} = \Delta x_1 \hat{\beta}_1 + \Delta x_2 \hat{\beta}_2 = (1)(125) + (0.32)(40) = 137.8$$

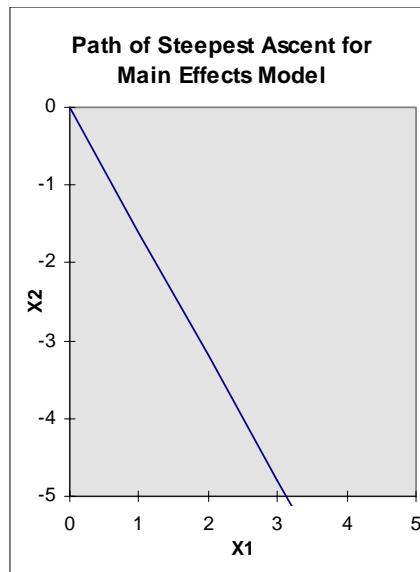

$$\# Steps = \frac{2500 - 2000}{137.8} = 3.63 \rightarrow 4$$

11-7 The path of steepest ascent is usually computed assuming that the model is truly first-order.; that is, there is no interaction. However, even if there is interaction, steepest ascent ignoring the interaction still usually produces good results. To illustrate, suppose that we have fit the model

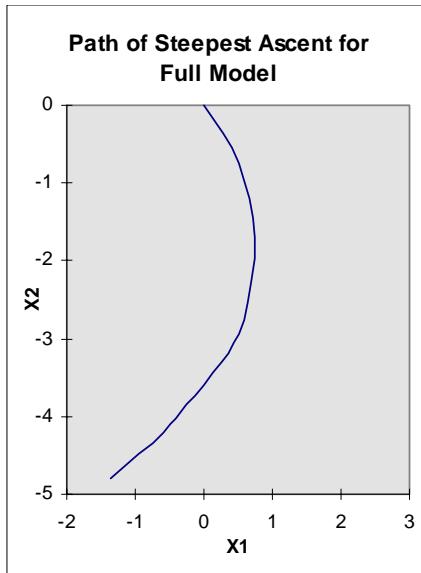

$$\hat{y} = 20 + 5x_1 - 8x_2 + 3x_1x_2$$

using coded variables ($-1 \leq x_1 \leq +1$)

- (a) Draw the path of steepest ascent that you would obtain if the interaction were ignored.

- (b) Draw the path of steepest ascent that you would obtain with the interaction included in the model. Compare this with the path found in part (a).

11-8 The data shown in the following table were collected in an experiment to optimize crystal growth as a function of three variables x_1 , x_2 , and x_3 . Large values of y (yield in grams) are desirable. Fit a second order model and analyze the fitted surface. Under what set of conditions is maximum growth achieved?

A ²	4.88	1	0.72	3.18	6.59	1.02
AB	6.00	1	0.92	3.83	8.17	1.00

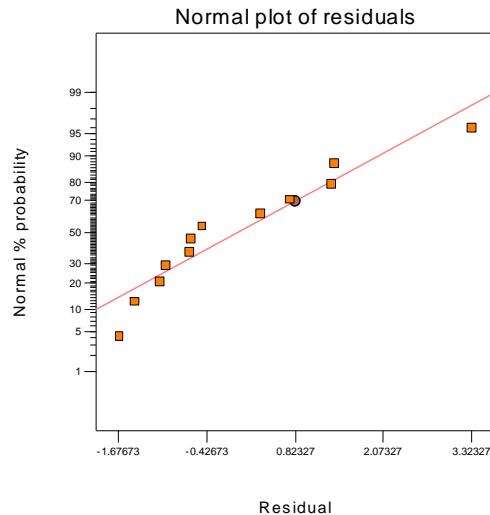

Final Equation in Terms of Coded Factors:

$$\begin{aligned} \text{Time} = \\ +40.68 \\ +1.28 * A \\ -4.82 * B \\ +4.88 * A^2 \\ +6.00 * A * B \end{aligned}$$

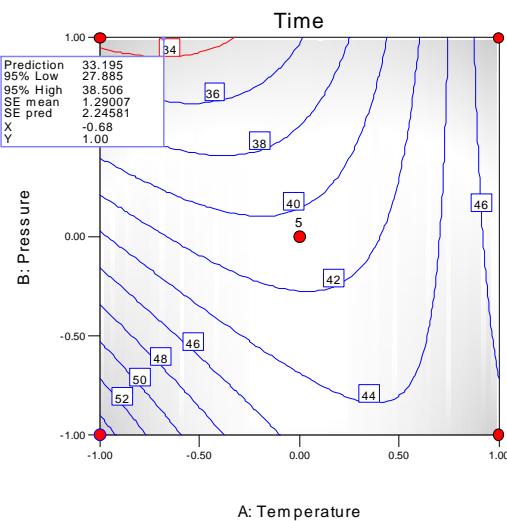

Final Equation in Terms of Actual Factors:

$$\begin{aligned} \text{Time} = \\ +40.67673 \\ +1.28033 * \text{Temperature} \\ -4.82374 * \text{Pressure} \\ +4.88218 * \text{Temperature}^2 \\ +6.00000 * \text{Temperature} * \text{Pressure} \end{aligned}$$

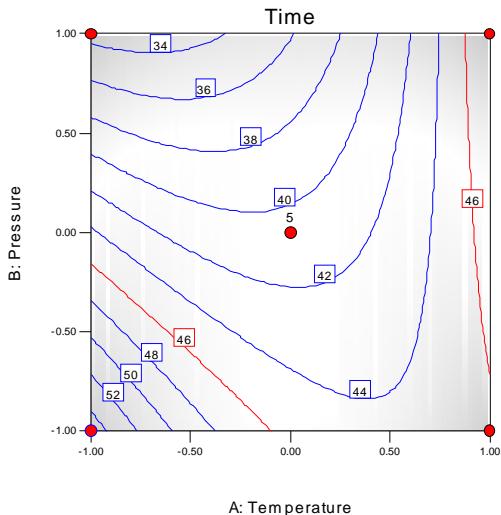

The lack of fit test is satisfactory as well as the following normal plot of residuals:

- (a) What operating conditions would you recommend if the objective is to minimize the filtration time?

- (b) What operating conditions would you recommend if the objective is to operate the process at a mean filtration time very close to 46?

There are two regions that enable a filtration time of 46. Either will suffice; however, higher temperatures and pressures typically have higher operating costs. We chose the operating conditions at the lower pressure and temperature as shown.

11-10 The hexagon design that follows is used in an experiment that has the objective of fitting a second-order model.

	x_1	x_2	y
	1	0	68
	0.5	$\sqrt{0.75}$	74
	-0.5	$\sqrt{0.75}$	65
	-1	0	60
	-0.5	$-\sqrt{0.75}$	63
	0.5	$-\sqrt{0.75}$	70
	0	0	58
	0	0	60
	0	0	57
	0	0	55
	0	0	69

(a) Fit the second-order model.

Final Equation in Terms of Coded Factors:

$$\begin{aligned} y = & \\ +59.80 & \\ +5.33 * A & \\ +1.73 * B & \\ +4.20 * A^2 & \\ +9.53 * B^2 & \\ +1.15 * A * B & \end{aligned}$$

- (a) Perform the canonical analysis. What type of surface has been found?

The full quadratic model is used in the following analysis because the reduced model is singular.

Solution		
Variable	Critical Value	
X1	-0.627658	
X2	-0.052829	
Predicted Value at Solution		58.080492

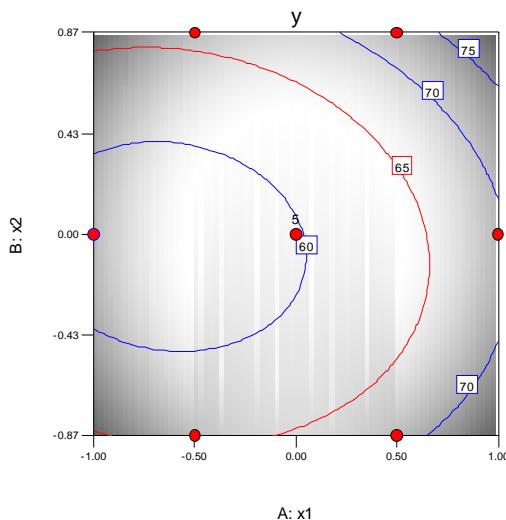

Eigenvalues and Eigenvectors		
Variable	9.5957	4.1382
X1	0.10640	0.99432
X2	0.99432	-0.10640

Since both eigenvalues are positive, the response is a minimum at the stationary point.

- (c) What operating conditions on x_1 and x_2 lead to the stationary point?

The stationary point is $(x_1, x_2) = (-0.62766, -0.05283)$

- (d) Where would you run this process if the objective is to obtain a response that is as close to 65 as possible?

Any value of x_1 and x_2 that give a point on the contour with value of 65 would be satisfactory.

11-11 An experimenter has run a Box-Behnken design and has obtained the results below, where the response variable is the viscosity of a polymer.

Level	Agitation			x_1	x_2	x_3
	Temp.	Rate	Pressure			
High	200	10.0	25	+1	+1	+1
Middle	175	7.5	20	0	0	0
Low	150	5.0	15	-1	-1	-1

Run	x_1	x_2	x_3	y_1
1	-1	-1	0	535
2	1	-1	0	580
3	-1	1	0	596
4	1	1	0	563
5	-1	0	-1	645
6	1	0	-1	458
7	-1	0	1	350
8	1	0	1	600
9	0	-1	-1	595

- (b) Perform the canonical analysis. What type of surface has been found?

Solution	
Variable	Critical Value
X1	2.1849596
X2	-0.871371
X3	2.7586015
Predicted Value at Solution	586.34437

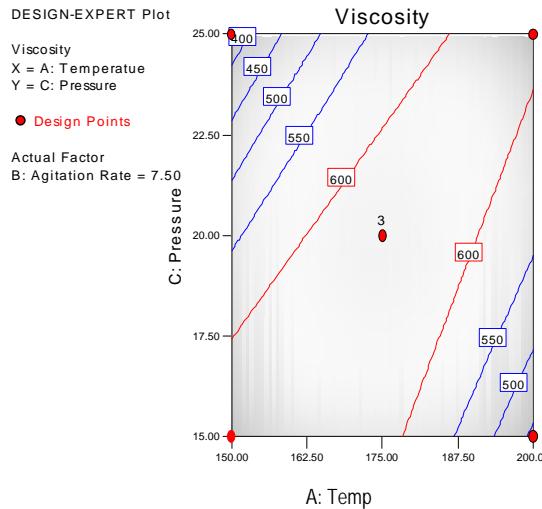

Eigenvalues and Eigenvectors			
Variable	20.9229	2.5208	-114.694
X1	-0.02739	0.58118	0.81331
X2	0.99129	-0.08907	0.09703
X3	0.12883	0.80888	-0.57368

The system is a saddle point.

- (c) What operating conditions on x_1 , x_2 , and x_3 lead to the stationary point?

The stationary point is $(x_1, x_2, x_3) = (2.18496, -0.87167, 2.75860)$. This is outside the design region. It would be necessary to either examine contour plots or use numerical optimization methods to find desired operating conditions.

- (d) What operating conditions would you recommend if it is important to obtain a viscosity that is as close to 600 as possible?

Any point on either of the contours showing a viscosity of 600 is satisfactory.

- 11-12** Consider the three-variable central composite design shown below. Analyze the data and draw conclusions, assuming that we wish to maximize conversion (y_1) with activity (y_2) between 55 and 60.

Run	Time (min)	Temperature (°C)	Catalyst (%)	Conversion (%) y_1	Activity y_2

The contour plots visually describe the models while the overlay plots identifies the acceptable region for the process.

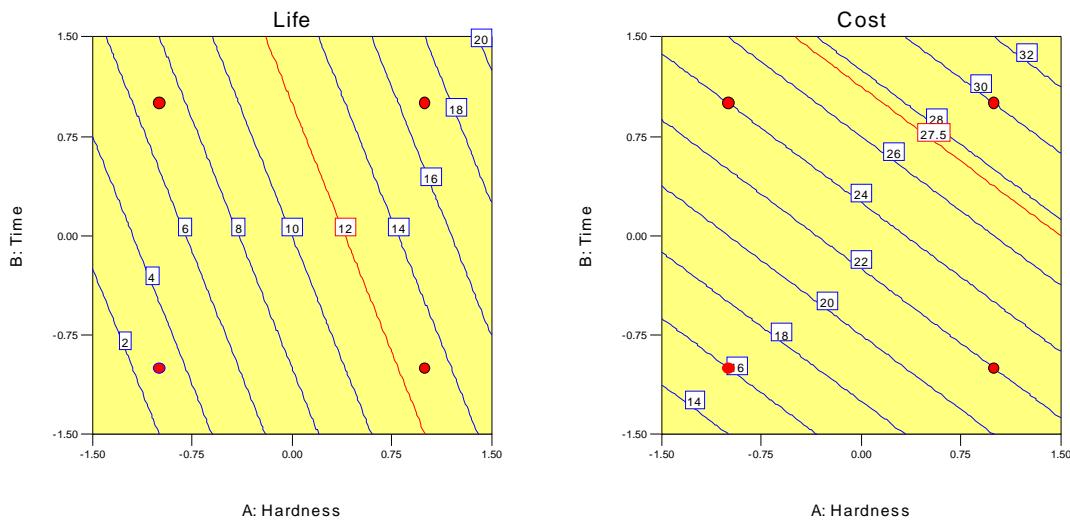

11-13 A manufacturer of cutting tools has developed two empirical equations for tool life in hours (y_1) and for tool cost in dollars (y_2). Both models are linear functions of steel hardness (x_1) and manufacturing time (x_2). The two equations are

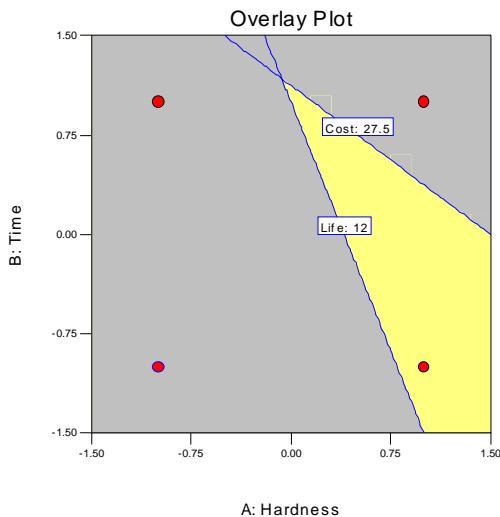

$$\hat{y}_1 = 10 + 5x_1 + 2x_2$$

$$\hat{y}_2 = 23 + 3x_1 + 4x_2$$

and both equations are valid over the range $-1.5 \leq x_1 \leq 1.5$. Unit tool cost must be below \$27.50 and life must exceed 12 hours for the product to be competitive. Is there a feasible set of operating conditions for this process? Where would you recommend that the process be run?

The contour plots below graphically describe the two models. The overlay plot identifies the feasible operating region for the process.

$$10 + 5x_1 + 2x_2 \geq 12$$

$$23 + 3x_1 + 4x_2 \leq 27.50$$

11-14 A central composite design is run in a chemical vapor deposition process, resulting in the experimental data shown below. Four experimental units were processed simultaneously on each run of the design, and the responses are the mean and variance of thickness, computed across the four units.

	x_1	x_2	\bar{y}	s^2
	-1	-1	360.6	6.689

The residual plots are much improved following the natural log transformation; however, the two runs still appear to be somewhat unusual and should be investigated further. They will be retained in the analysis.

- (d) Suppose you want the mean thickness to be in the interval 450 ± 25 . Find a set of operating conditions that achieve the objective and simultaneously minimize the variance.

The contour plots describe the two models while the overlay plot identifies the acceptable region for the process.

- (e) Discuss the variance minimization aspects of part (d). Have you minimized total process variance?

The within run variance has been minimized; however, the run-to-run variation has not been minimized in the analysis. This may not be the most robust operating conditions for the process.

11-15 Verify that an orthogonal first-order design is also first-order rotatable.

To show that a first order orthogonal design is also first order rotatable, consider

$$V(\hat{y}) = V(\hat{\beta}_0 + \sum_{i=1}^k \hat{\beta}_i x_i) = V(\hat{\beta}_0) + \sum_{i=1}^k x_i^2 V(\hat{\beta}_i)$$

since all covariances between $\hat{\beta}_i$ and $\hat{\beta}_j$ are zero, due to design orthogonality. Furthermore, we have:

$$\begin{aligned} V(\hat{\beta}_0) &= V(\hat{\beta}_1) = V(\hat{\beta}_2) = \dots = V(\hat{\beta}_k) = \frac{\sigma^2}{n}, \text{ so} \\ V(\hat{y}) &= \frac{\sigma^2}{n} + \frac{\sigma^2}{n} \sum_{i=1}^k x_i^2 \\ V(\hat{y}) &= \frac{\sigma^2}{n} \left(1 + \frac{\sigma^2}{n} \sum_{i=1}^k x_i^2 \right) \end{aligned}$$

which is a function of distance from the design center (i.e. $\mathbf{x}=\mathbf{0}$), and not direction. Thus the design must be rotatable. Note that n is, in general, the number of points in the exterior portion of the design. If there are n_c centerpoints, then $V(\hat{\beta}_0) = \frac{\sigma^2}{(n+n_c)}$.

11-16 Show that augmenting a 2^k design with n_c center points does not affect the estimates of the β_i ($i=1, 2, \dots, k$), but that the estimate of the intercept β_0 is the average of all $2^k + n_c$ observations.

In general, the \mathbf{X} matrix for the 2^k design with n_c center points and the \mathbf{y} vector would be:

$$\mathbf{X} = \begin{array}{c} \begin{matrix} \beta_0 & \beta_1 & \beta_2 & \dots & \beta_k \\ \left[\begin{array}{ccccc} 1 & -1 & -1 & \dots & -1 \\ 1 & 1 & -1 & \dots & -1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & 1 & \dots & 1 \end{array} \right] & \leftarrow \text{The upper half of the matrix is the usual } \pm 1 \text{ notation of the } 2^k \text{ design} \\ \hline & \left[\begin{array}{ccccc} 1 & 0 & 0 & \dots & 0 \\ 1 & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 0 & 0 & \dots & 0 \end{array} \right] & \leftarrow \text{The lower half of the matrix represents the center points (} n_c \text{ rows)} \end{array} \\ \\ \mathbf{y} = \left[\begin{array}{c} y_1 \\ y_2 \\ \vdots \\ y_{2^k} \\ \hline n_{0_1} \\ \vdots \\ n_{0_c} \end{array} \right] \leftarrow 2^k + n_c \text{ observations} \quad \mathbf{X}'\mathbf{X} = \left[\begin{array}{cccc} 2^k + n_c & 0 & \dots & 0 \\ & 2^k & \dots & 0 \\ & & \ddots & \vdots \\ & & & 2^k \end{array} \right] \quad \mathbf{X}'\mathbf{y} = \left[\begin{array}{c} g_0 \\ g_1 \\ g_2 \\ \vdots \\ g_k \end{array} \right] \leftarrow \begin{array}{l} \text{Grand total of} \\ \text{all } 2^k + n_c \text{ observations} \end{array} \quad \leftarrow \text{usual contrasts from } 2^k \end{array}$$

Therefore, $\hat{\beta}_0 = \frac{g_0}{2^k + n_c}$, which is the average of all $(2^k + n_c)$ observations, while $\hat{\beta}_i = \frac{g_i}{2^k}$, which does not depend on the number of center points, since in computing the contrasts g_i , all observations at the center are multiplied by zero.

11-17 The rotatable central composite design. It can be shown that a second-order design is rotatable if $\sum_{u=1}^n x_{iu}^a x_{ju}^b = 0$ if a or b (or both) are odd and if $\sum_{u=1}^n x_{iu}^4 = 3 \sum_{u=1}^n x_{iu}^2 x_{ju}^2$. Show that for the central composite design these conditions lead to $\alpha = (n_f)^{1/4}$ for rotatability, where n_f is the number of points in the factorial portion.

The balance between +1 and -1 in the factorial columns and the orthogonality among certain column in the \mathbf{X} matrix for the central composite design will result in all odd moments being zero. To solve for α use the following relations:

$$\sum_{u=1}^n x_{iu}^4 = n_f + 2\alpha^4, \quad \sum_{u=1}^n x_{iu}^2 x_{ju}^2 = n_f$$

then

$$\begin{aligned}\sum_{u=1}^n x_{iu}^4 &= 3 \sum_{u=1}^n x_{iu}^2 x_{ju}^2 \\ n_f + 2\alpha^4 &= 3(n_f) \\ 2\alpha^4 &= 2n_f \\ \alpha^4 &= n_f \\ \alpha &= \sqrt[4]{n_f}\end{aligned}$$

11-18 Verify that the central composite design shown below blocks orthogonally.

Block 1			Block 2			Block 3		
x_1	x_2	x_3	x_1	x_2	x_3	x_1	x_2	x_3
0	0	0	0	0	0	-1.633	0	0
0	0	0	0	0	0	1.633	0	0
1	1	1	1	1	-1	0	-1.633	0
1	-1	-1	1	-1	1	0	1.633	0
-1	-1	1	-1	1	1	0	0	-1.633
-1	1	-1	-1	-1	-1	0	0	1.633
						0	0	0
						0	0	0

Note that each block is an orthogonal first order design, since the cross products of elements in different columns add to zero for each block. To verify the second condition, choose a column, say column x_2 .

Now

$$\sum_{u=1}^k x_{2u}^2 = 13.334, \text{ and } n=20$$

For blocks 1 and 2,

$$\sum_m x_{2m}^2 = 4, n_m=6$$

So

$$\begin{aligned}\frac{\sum_m x_{2m}^2}{\sum_{u=1}^n x_{2u}^2} &= n_m = 6 \\ \frac{4}{13.334} &= \frac{6}{20} \\ 0.3 &= 0.3\end{aligned}$$

and condition 2 is satisfied by blocks 1 and 2. For block 3, we have

$$\sum_m x_{2m}^2 = 5.334, n_m = 8, \text{ so}$$

$$\frac{\sum_m x_{2m}^2}{\sum_{u=1}^n x_{2u}^2} = \frac{n_m}{n}$$

$$\frac{5.334}{13.334} = \frac{8}{20}$$

$$0.4 = 0.4$$

And condition 2 is satisfied by block 3. Similar results hold for the other columns.

11-19 Blocking in the central composite design. Consider a central composite design for $k = 4$ variables in two blocks. Can a rotatable design always be found that blocks orthogonally?

To run a central composite design in two blocks, assign the n_f factorial points and the n_{c1} center points to block 1 and the 2^k axial points plus n_{c2} center points to block 2. Both blocks will be orthogonal first order designs, so the first condition for orthogonal blocking is satisfied.

The second condition implies that

$$\frac{\sum_m x_{im}^2 (\text{block 1})}{\sum_m x_{im}^2 (\text{block 2})} = \frac{n_f + n_{c1}}{2k + n_{c2}}$$

However, $\sum_m x_{im}^2 = n_f$ in block 1 and $\sum_m x_{im}^2 = 2\alpha^2$ in block 2, so

$$\frac{n_f}{2\alpha^2} = \frac{n_f + n_{c1}}{2k + n_{c2}}$$

Which gives:

$$\alpha = \left[\frac{n_f (2k + n_{c2})}{2(n_f + n_{c1})} \right]^{\frac{1}{2}}$$

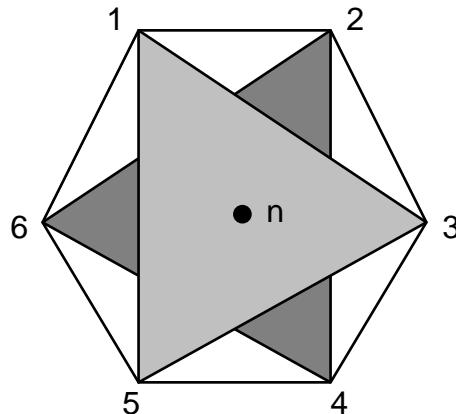

Since $\alpha = \sqrt[4]{n_f}$ if the design is to be rotatable, then the design must satisfy

$$n_f = \left[\frac{n_f (2k + n_{c2})}{2(n_f + n_{c1})} \right]^2$$

It is not possible to find rotatable central composite designs which block orthogonally for all k . For example, if $k=3$, the above condition cannot be satisfied. For $k=2$, there must be an equal number of center points in each block, i.e. $n_{c1} = n_{c2}$. For $k=4$, we must have $n_{c1} = 4$ and $n_{c2} = 2$.

11-20 How could a hexagon design be run in two orthogonal blocks?

The hexagonal design can be blocked as shown below. There are $n_{c1} = n_{c2} = n_c$ center points with n_c even.

Put the points 1,3, and 5 in block 1 and 2,4, and 6 in block 2. Note that each block is a simplex.

11-21 Yield during the first four cycles of a chemical process is shown in the following table. The variables are percent concentration (x_1) at levels 30, 31, and 32 and temperature (x_2) at 140, 142, and 144°F. Analyze by EVOP methods.

$CIM = \frac{1}{2}(\bar{y}_3 + \bar{y}_4 + \bar{y}_2 + \bar{y}_5 - 4\bar{y}_1) = 1.46$	

From studying cycles 3 and 4, it is apparent that A (and possibly B) has a significant effect. A new phase should be started following cycle 3 or 4.

11-22 Suppose that we approximate a response surface with a model of order d_1 , such as $\mathbf{y}=\mathbf{X}_1\boldsymbol{\beta}_1+\boldsymbol{\epsilon}$, when the true surface is described by a model of order $d_2>d_1$; that is $E(\mathbf{y})=\mathbf{X}_1\boldsymbol{\beta}_{1+}\mathbf{X}_2\boldsymbol{\beta}_2$.

- (a) Show that the regression coefficients are biased, that is, that $E(\hat{\boldsymbol{\beta}}_1)=\boldsymbol{\beta}_1+\mathbf{A}\boldsymbol{\beta}_2$, where $\mathbf{A}=(\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1\mathbf{X}_2$. \mathbf{A} is usually called the alias matrix.

$$\begin{aligned}
 E[\hat{\boldsymbol{\beta}}_1] &= E\left[(\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1\mathbf{y}\right] \\
 &= (\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1E[\mathbf{y}] \\
 &= (\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1(\mathbf{X}_1\boldsymbol{\beta}_1 + \mathbf{X}_2\boldsymbol{\beta}_2) \\
 &= (\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1\mathbf{X}_1\boldsymbol{\beta}_1 + (\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1\mathbf{X}_2\boldsymbol{\beta}_2 \\
 &= \boldsymbol{\beta}_1 + \mathbf{A}\boldsymbol{\beta}_2
 \end{aligned}$$

where $\mathbf{A}=(\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1\mathbf{X}_2$

- (a) If $d_1=1$ and $d_2=2$, and a full 2^k is used to fit the model, use the result in part (a) to determine the alias structure.

In this situation, we have assumed the true surface to be first order, when it is really second order. If a full factorial is used for $k=2$, then

$$\mathbf{X}_1 = \begin{bmatrix} 1 & -1 & -1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \\ 1 & 1 & 1 \end{bmatrix} \quad \mathbf{X}_2 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & -1 \\ 1 & 1 & -1 \\ 1 & 1 & 1 \end{bmatrix} \quad \text{and} \quad \mathbf{A} = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

$$\text{Then, } \mathbf{E}[\hat{\beta}_1] = \mathbf{E}\begin{bmatrix} \hat{\beta}_0 \\ \hat{\beta}_1 \\ \hat{\beta}_2 \end{bmatrix} = \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \end{bmatrix} + \begin{bmatrix} 1 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \beta_{11} \\ \beta_{22} \\ \beta_{12} \end{bmatrix} = \begin{bmatrix} \beta_0 + \beta_{11} + \beta_{22} \\ \beta_1 \\ \beta_2 \end{bmatrix}$$

The pure quadratic terms bias the intercept.

- (b) If $d_1=1$, $d_2=2$ and $k=3$, find the alias structure assuming that a 2^{3-1} design is used to fit the model.

$$\mathbf{X}_1 = \begin{bmatrix} \beta_0 & \beta_1 & \beta_2 & \beta_3 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \quad \mathbf{X}_2 = \begin{bmatrix} \beta_{11} & \beta_{22} & \beta_{33} & \beta_{12} & \beta_{13} & \beta_{23} \\ 1 & 1 & 1 & 1 & -1 & -1 \\ 1 & 1 & 1 & -1 & -1 & 1 \\ 1 & 1 & 1 & -1 & 1 & -1 \\ 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \quad \text{and } \mathbf{A} = \begin{bmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \end{bmatrix}$$

$$\text{Then, } \mathbf{E}[\hat{\beta}_1] = \mathbf{E}\begin{bmatrix} \hat{\beta}_0 \\ \hat{\beta}_1 \\ \hat{\beta}_2 \\ \hat{\beta}_3 \end{bmatrix} = \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix} + \begin{bmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \beta_{11} \\ \beta_{22} \\ \beta_{33} \\ \beta_{12} \\ \beta_{13} \\ \beta_{23} \end{bmatrix} = \begin{bmatrix} \beta_0 + \beta_{11} + \beta_{22} + \beta_{33} \\ \beta_1 + \beta_{23} \\ \beta_2 + \beta_{13} \\ \beta_3 + \beta_{12} \\ \beta_{23} \end{bmatrix}$$

- (d) If $d_1=1$, $d_2=2$, $k=3$, and the simplex design in Problem 11-3 is used to fit the model, determine the alias structure and compare the results with part (c).

$$\mathbf{X}_1 = \begin{bmatrix} \beta_0 & \beta_1 & \beta_2 & \beta_3 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \quad \mathbf{X}_2 = \begin{bmatrix} \beta_{11} & \beta_{22} & \beta_{33} & \beta_{12} & \beta_{13} & \beta_{23} \\ 0 & 2 & 1 & 0 & 0 & -\sqrt{2} \\ 2 & 0 & 1 & 0 & -\sqrt{2} & 0 \\ 0 & 2 & 1 & 0 & 0 & -\sqrt{2} \\ 2 & 0 & 1 & 0 & -\sqrt{2} & 0 \end{bmatrix} \quad \text{and } \mathbf{A} = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \\ 1 & -1 & 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\text{Then, } \mathbf{E}[\hat{\beta}_1] = \mathbf{E}\begin{bmatrix} \hat{\beta}_0 \\ \hat{\beta}_1 \\ \hat{\beta}_2 \\ \hat{\beta}_3 \end{bmatrix} = \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix} + \begin{bmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \\ 1 & -1 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \beta_{11} \\ \beta_{22} \\ \beta_{33} \\ \beta_{12} \\ \beta_{13} \\ \beta_{23} \end{bmatrix} = \begin{bmatrix} \beta_0 + \beta_{11} + \beta_{22} + \beta_{33} \\ \beta_1 + \beta_{13} \\ \beta_2 - \beta_{23} \\ \beta_3 + \beta_{11} - \beta_{22} \\ \beta_{23} \end{bmatrix}$$

Notice that the alias structure is different from that found in the previous part for the 2^{3-1} design. In general, the \mathbf{A} matrix will depend on which simplex design is used.

- 11-23** Suppose that you need to design an experiment to fit a quadratic model over the region $-1 \leq x_i \leq +1$, $i=1,2$ subject to the constraint $x_1 + x_2 \leq 1$. If the constraint is violated, the process will not work properly. You can afford to make no more than $n=12$ runs. Set up the following designs:

- (a) An “inscribed” CCD with center points at $x_1 = x_2 = 0$

x_1	x_2
-0.5	-0.5
0.5	-0.5
-0.5	0.5
0.5	0.5
-0.707	0
0.707	0
0	-0.707
0	0.707
0	0
0	0
0	0
0	0

- (a)* An “inscribed” CCD with center points at $x_1 = x_2 = -0.25$ so that a larger design could be fit within the constrained region

x_1	x_2
-1	-1
0.5	-1
-1	0.5
0.5	0.5
-1.664	-0.25
1.164	-0.25
-0.25	-1.664
-0.25	1.164
-0.25	-0.25
-0.25	-0.25
-0.25	-0.25
-0.25	-0.25

- (a) An “inscribed” 3^2 factorial with center points at $x_1 = x_2 = -0.25$

x_1	x_2
-1	-1
-0.25	-1
0.5	-1
-1	-0.25
-0.25	-0.25
0.5	-0.25
-1	0.5
-0.25	0.5
0.5	0.5
-0.25	-0.25
-0.25	-0.25
-0.25	-0.25

- (a) A D-optimal design.

x_1	x_2
-1	-1
1	-1
-1	1
1	0
0	1
0	0
-1	0
0	-1
0.5	0.5
-1	-1
1	-1
-1	1

- (a) A modified D-optimal design that is identical to the one in part (c), but with all replicate runs at the design center.

x_1	x_2
1	0
0	0
0	1
-1	-1
1	-1
-1	1
-1	0
0	-1
0.5	0.5
0	0

- (a) Evaluate the $\left|(\mathbf{X}'\mathbf{X})^{-1}\right|$ criteria for each design.

	(a)	(a)*	(b)	(c)	(d)
$\left (\mathbf{X}'\mathbf{X})^{-1}\right $	0.5	0.00005248	0.007217	0.0001016	0.0002294

- (a) Evaluate the D-efficiency for each design relative to the D-optimal design in part (c).

	(a)	(a)*	(b)	(c)	(d)
D-efficiency	24.25%	111.64%	49.14%	100.00%	87.31%

- (a) Which design would you prefer? Why?

The offset CCD, (a)*, is the preferred design based on the D-efficiency. Not only is it better than the D-optimal design, (c), but it maintains the desirable design features of the CCD.

11-24 Consider a 2^3 design for fitting a first-order model.

- (a) Evaluate the D-criterion $\left|(\mathbf{X}'\mathbf{X})^{-1}\right|$ for this design.

$$\left|(\mathbf{X}'\mathbf{X})^{-1}\right| = 2.441E-4$$

- (b) Evaluate the A-criterion $tr(\mathbf{X}'\mathbf{X})^{-1}$ for this design.

$$tr(\mathbf{X}'\mathbf{X})^{-1} = 0.5$$

- (c) Find the maximum scaled prediction variance for this design. Is this design G-optimal?

$$v(\mathbf{x}) = \frac{NVar(\hat{y}(\mathbf{x}))}{\sigma^2} = N\mathbf{x}'^{(1)}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}^{(1)} = 4. \text{ Yes, this is a G-optimal design.}$$

11-25 Repeat Problem 11-24 using a first order model with the two-factor interaction.

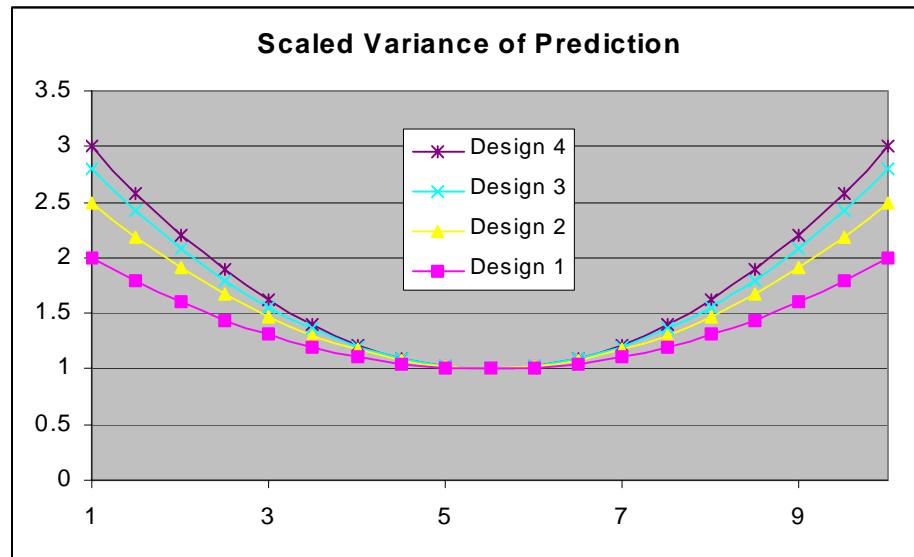

$$\left|(\mathbf{X}'\mathbf{X})^{-1}\right| = 4.768E-7$$

$$tr(\mathbf{X}'\mathbf{X})^{-1} = 0.875$$

$$v(\mathbf{x}) = \frac{NVar(\hat{y}(\mathbf{x}))}{\sigma^2} = N\mathbf{x}'^{(1)}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}^{(1)} = 7. \text{ Yes, this is a G-optimal design.}$$

11-26 A chemical engineer wishes to fit a calibration curve for a new procedure used to measure the concentration of a particular ingredient in a product manufactured in his facility. Twelve samples can be prepared, having known concentration. The engineer's interest is in building a model for the measured concentrations. He suspects that a linear calibration curve will be adequate to model the measured concentration as a function of the known concentrations; that is, where x is the actual concentration. Four experimental designs are under consideration. Design 1 consists of 6 runs at known concentration 1 and 6 runs at known concentration 10. Design 2 consists of 4 runs at concentrations 1, 5.5, and 10. Design 3 consists of 3 runs at concentrations 1, 4, 7, and 10. Finally, design 4 consists of 3 runs at concentrations 1 and 10 and 6 runs at concentration 5.5.

- (a) Plot the scaled variance of prediction for all four designs on the same graph over the concentration range. Which design would be preferable, in your opinion?

Because it has the lowest scaled variance of prediction at all points in the design space with the exception of 5.5, Design 1 is preferred.

- (b) For each design calculate the determinant of $(\mathbf{X}'\mathbf{X})^{-1}$. Which design would be preferred according to the “D” criterion?

Design	$ (\mathbf{X}'\mathbf{X})^{-1} $
1	0.000343
2	0.000514
3	0.000617
4	0.000686

Design 1 would be preferred.

- (c) Calculate the D-efficiency of each design relative to the “best” design that you found in part b.

Design	D-efficiency
1	100.00%
2	81.65%
3	74.55%
4	70.71%

- (a) For each design, calculate the average variance of prediction over the set of points given by $x = 1, 1.5, 2, 2.5, \dots, 10$. Which design would you prefer according to the V-criterion?

Average Variance of Prediction		
Design	Actual	Coded
1	1.3704	0.1142
2	1.5556	0.1296
3	1.6664	0.1389
4	1.7407	0.1451

Design 1 is still preferred based on the V-criterion.

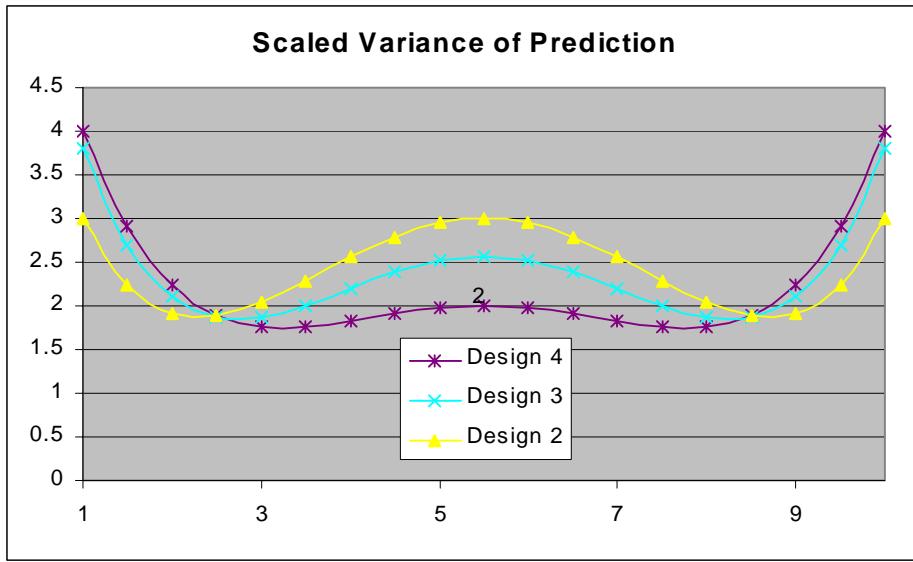

(e) Calculate the V-efficiency of each design relative to the best design you found in part (d).

Design	V-efficiency
1	100.00%
2	88.10%
3	82.24%
4	78.72%

(f) What is the G-efficiency of each design?

Design	G-efficiency
1	100.00%
2	80.00%
3	71.40%
4	66.70%

11-27 Rework Problem 11-26 assuming that the model the engineer wishes to fit is a quadratic. Obviously, only designs 2, 3, and 4 can now be considered.

Based on the plot, the preferred design would depend on the region of interest. Design 4 would be preferred if the center of the region was of interest; otherwise, Design 2 would be preferred.

Design	$ (\mathbf{X}'\mathbf{X})^{-1} $
2	4.704E-07
3	6.351E-07
4	5.575E-07

Design 2 is preferred based on $|(\mathbf{X}'\mathbf{X})^{-1}|$.

Design	D-efficiency
2	100.00%

3	90.46%
4	94.49%

Average Variance of Prediction

Design	Actual	Coded
2	2.441	0.2034
3	2.393	0.1994
4	2.242	0.1869

Design 4 is preferred.

Design	V-efficiency
2	91.89%
3	93.74%
4	100.00%

Design	G-efficiency
2	100.00%
3	79.00%
4	75.00%

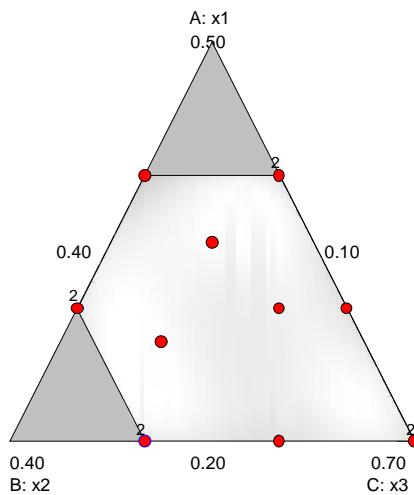

11-28 An experimenter wishes to run a three-component mixture experiment. The constraints are the components proportions are as follows:

$$\begin{aligned}0.2 \leq x_1 &\leq 0.4 \\0.1 \leq x_2 &\leq 0.3 \\0.4 \leq x_3 &\leq 0.7\end{aligned}$$

- (a) Set up an experiment to fit a quadratic mixture model. Use $n=14$ runs, with 4 replicates. Use the D-criteria.

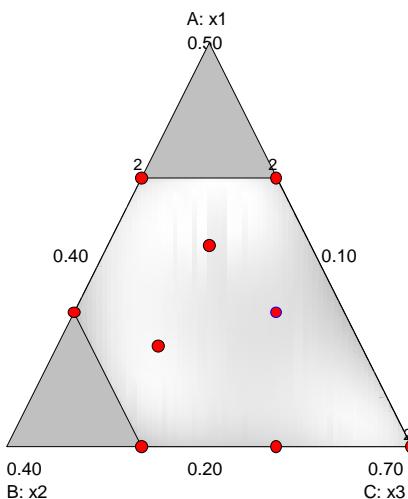

Std	x1	x2	x3
1	0.2	0.3	0.5
2	0.3	0.3	0.4
3	0.3	0.15	0.55
4	0.2	0.1	0.7
5	0.4	0.2	0.4
6	0.4	0.1	0.5
7	0.2	0.2	0.6
8	0.275	0.25	0.475
9	0.35	0.175	0.475
10	0.3	0.1	0.6
11	0.2	0.3	0.5
12	0.3	0.3	0.4
13	0.2	0.1	0.7
14	0.4	0.1	0.5

- (a) Draw the experimental design region.

- (c) Set up an experiment to fit a quadratic mixture model with $n=12$ runs, assuming that three of these runs are replicated. Use the D-criterion.

Std	x_1	x_2	x_3
1	0.3	0.15	0.55
2	0.2	0.3	0.5
3	0.3	0.3	0.4
4	0.2	0.1	0.7
5	0.4	0.2	0.4
6	0.4	0.1	0.5
7	0.2	0.2	0.6
8	0.275	0.25	0.475
9	0.35	0.175	0.475
10	0.2	0.1	0.7
11	0.4	0.1	0.5
12	0.4	0.2	0.4

(d) Comment on the two designs you have found.

The design points are the same for both designs except that the edge center on the x_1-x_3 edge is not included in the second design. None of the replicates for either design are in the center of the experimental region. The experimental runs are fairly uniformly spaced in the design region.

11-29 Myers and Montgomery (2002) describe a gasoline blending experiment involving three mixture components. There are no constraints on the mixture proportions, and the following 10 run design is used.

Design Point	x_1	x_2	x_3	$y(\text{mpg})$
1	1	0	0	24.5, 25.1
2	0	1	0	24.8, 23.9
3	0	0	1	22.7, 23.6
4	$\frac{1}{2}$	$\frac{1}{2}$	0	25.1
5	$\frac{1}{2}$	0	$\frac{1}{2}$	24.3
6	0	$\frac{1}{2}$	$\frac{1}{2}$	23.5
7	$\frac{1}{3}$	$\frac{1}{3}$	$\frac{1}{3}$	24.8, 24.1
8	$\frac{2}{3}$	$\frac{1}{6}$	$\frac{1}{6}$	24.2
9	$\frac{1}{6}$	$\frac{2}{3}$	$\frac{1}{6}$	23.9
10	$\frac{1}{6}$	$\frac{1}{6}$	$\frac{2}{3}$	23.7

(a) What type of design did the experimenters use?

A simplex centroid design was used.

(b) Fit a quadratic mixture model to the data. Is this model adequate?

Design Expert Output

ANOVA for Mixture Quadratic Model					
Analysis of variance table [Partial sum of squares]					
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F

Final Equation in Terms of Real Components:

$$y = +24.93048 * x_1 + 24.35048 * x_2 + 23.19048 * x_3$$

(c) Plot the response surface contours. What blend would you recommend to maximize the MPG?

To maximize the miles per gallon, the recommended blend is $x_1 = 1$, $x_2 = 0$, and $x_3 = 0$.

Chapter 12

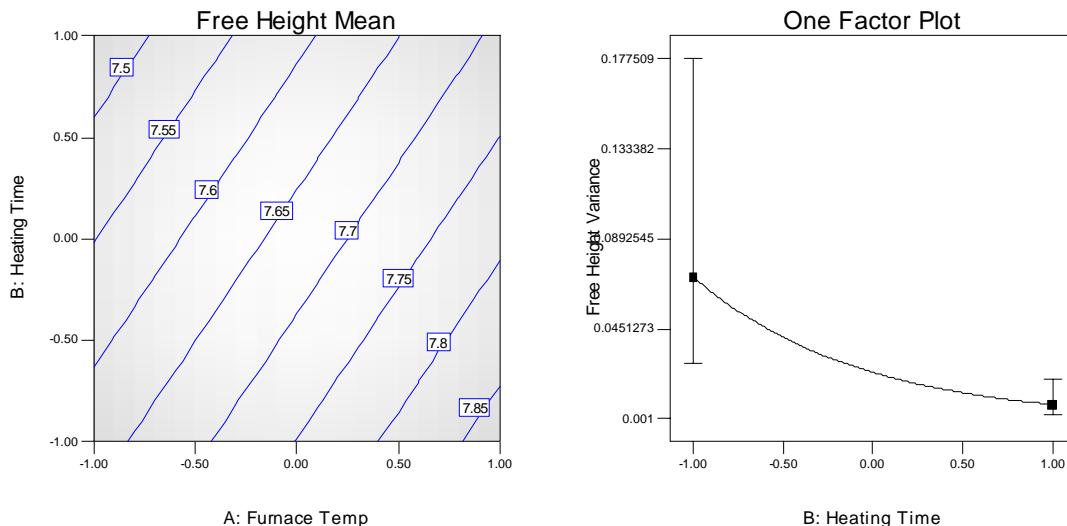

Robust Parameter Design and Process Robustness Studies

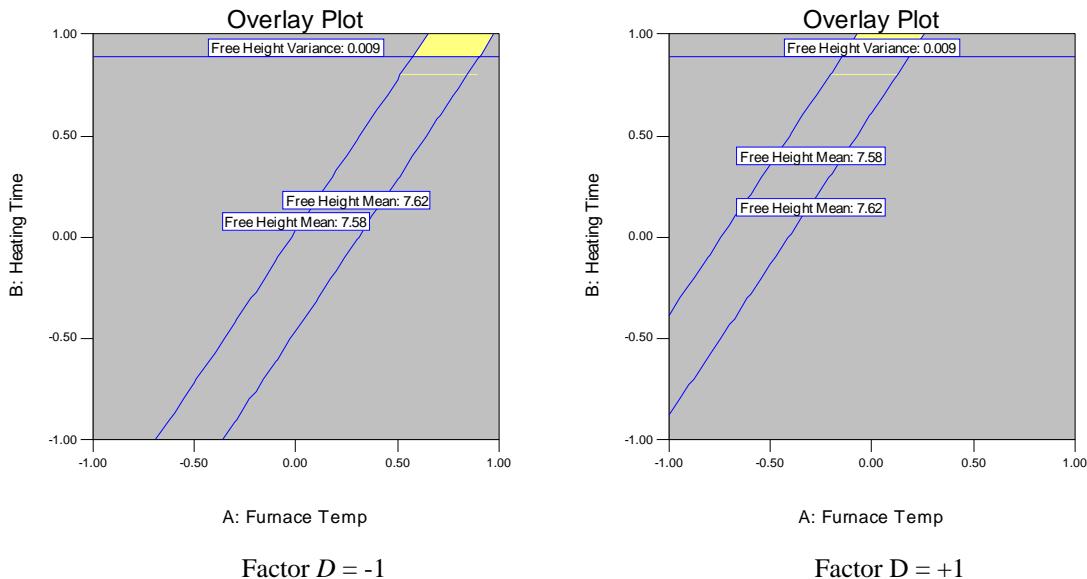

Solutions

12-1 Reconsider the leaf spring experiment in Table 12-1. Suppose that the objective is to find a set of conditions where the mean free height is as close as possible to 7.6 inches with a variance of free height as small as possible. What conditions would you recommend to achieve these objectives?

A	B	C	D	E(-)	E(+)	\bar{y}	s^2

+	+	+	+	7.56, 7.81, 7.69	7.81, 7.50, 7.59	7.66	0.017

By overlaying the contour plots for Free Height Mean and the Free Height Variance, optimal solutions can be found. To minimize the variance, factor B must be at the high level while factors A and D are adjusted to assure a mean of 7.6. The two overlay plots below set factor D at both low and high levels. Therefore, a mean as close as possible to 7.6 with minimum variance of 0.008 can be achieved at $A = 0.78$, $B = +1$, and $D = -1$. This can also be achieved with $A = +0.07$, $B = +1$, and $D = +1$.

12-2 Consider the bottle filling experiment in Problem 6-18. Suppose that the percentage of carbonation (A) is a noise variable ($\sigma_z^2 = 1$ in coded units).

(a) Fit the response model to these data. Is there a robust design problem?

The following is the analysis of variance with all terms in the model followed by a reduced model. Because the noise factor A is significant, and the AB interaction is moderately significant, there is a robust design problem.

Design Expert Output

Response: Fill Deviation ANOVA for Response Surface Reduced Cubic Model Analysis of variance table [Partial sum of squares]					
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F
Cor Total	300.05	3

Cor Total	78.00	15			not significant

The Model F-value of 26.84 implies there is a 0.01% chance that a "Model F-Value" this large could occur due to noise.

Std. Dev.	0.81	R-Squared	0.9071
Mean	1.00	Adj R-Squared	0.8733
C.V.	81.18	Pred R-Squared	0.8033
PRESS	15.34	Adeq Precision	15.424

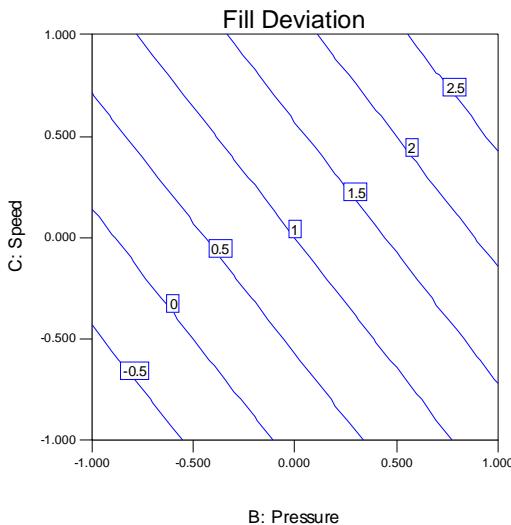

Final Equation in Terms of Coded Factors:

$$\begin{aligned} \text{Fill Deviation} = & \\ & +1.00 \\ & +1.50 * A \\ & +1.13 * B \\ & +0.88 * C \\ & +0.38 * A * B \end{aligned}$$

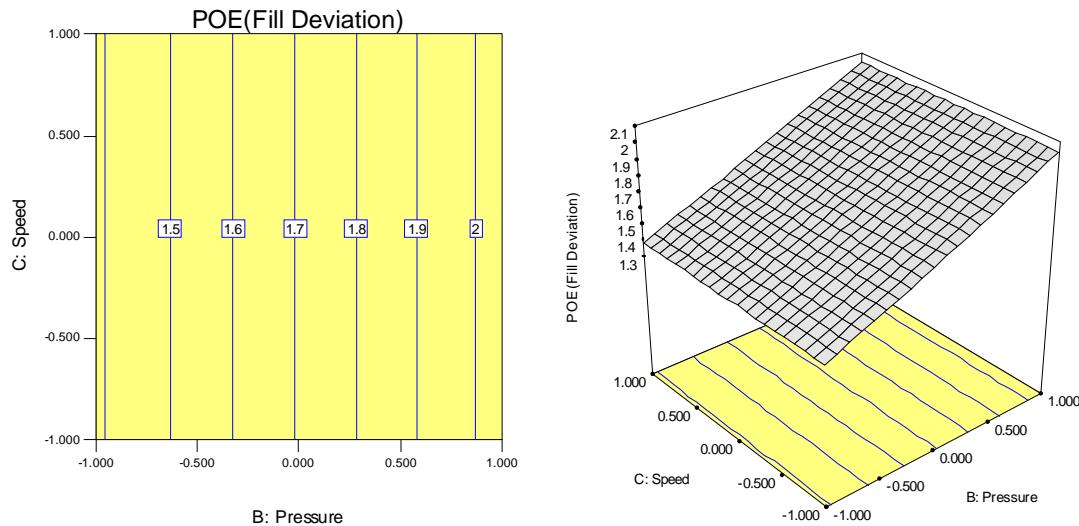

- (b) Find the mean model and either the variance model or the POE.

From the final equation shown in the above analysis, the mean model and corresponding contour plot is shown below.

$$E_z[y(\mathbf{x}, z_l)] = 1 + 1.13x_2 + 0.88x_3$$

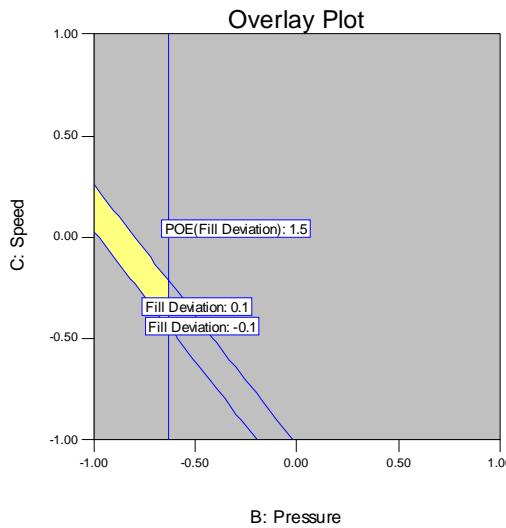

Contour and 3-D plots of the POE are shown below.

- (c) Find a set of conditions that result in mean fill deviation as close to zero as possible with minimum transmitted variance.

The overlay plot below identifies a an operating region for pressure and speed that in a mean fill deviation as close to zero as possible with minimum transmitted varianc.

- 12-3** Consider the experiment in Problem 11-12. Suppose that temperature is a noise variable ($\sigma_z^2 = 1$ in coded units). Fit response models for both responses. Is there a robust design problem with respect to both responses? Find a set of conditions that maximize conversion with activity between 55 and 60 and that minimize variability transmitted from temperature.

The analysis and models as found in problem 11-12 are shown below for both responses. There is a robust design problem with regards to the conversion response because of the significance of factor B , temperature, and the BC interaction. However, temperature is not significant in the analysis of the second response, activity.

Final Equation in Terms of Coded Factors:

$$\text{Activity} = \\ +59.95 \\ +3.58 * A \\ +2.23 * C \\ +0.82 * A^2$$

The following contour plots of conversion, activity, and POE and the corresponding optimization plot identify a region where conversion is maximized, activity is between 55 and 60, and the transmitted variability from temperature is minimized. Factor A is set at 0.5 while C is set at 0.4.

12-4 Reconsider the leaf spring experiment from Table 12-1. Suppose that factors A , B and C are controllable variables, and that factors D and E are noise factors. Set up a crossed array design to investigate this problem, assuming that all of the two-factor interactions involving the controllable variables are thought to be important. What type of design have you obtained?

The following experimental design has a 2^3 inner array for the controllable variables and a 2^2 outer array for the noise factors. A total of 32 runs are required.

Inner Array			Outer Array				
A	B	C	D	-1	1	-1	1

1	-1	1					
-1	1	1					
1	1	1					

12-5 Continuation of Problem 12-4. Reconsider the leaf spring experiment from Table 12-1. Suppose that A , B and C are controllable factors and that factors D and E are noise factors. Show how a combined array design can be employed to investigate this problem that allows all two-factor interactions to be estimated and only require 16 runs. Compare this with the crossed array design from Problem 12-5. Can you see how in general combined array designs that have fewer runs than crossed array designs?

The following experiment is a 2^{5-1} fractional factorial experiment where the controllable factors are A , B , and C and the noise factors are D and E . Only 16 runs are required versus the 32 runs required for the crossed array design in problem 12-4.

12-6 Consider the connector pull-off force experiment shown in Table 12-2. What main effects and interactions involving the controllable variables can be estimated with this design? Remember that all of the controllable variables are quantitative factors.

The design in Table 12-2 contains a 3^{4-2} inner array for the controllable variables. This is a resolution III design which aliases the main effects with two factor interactions. The alias table below identifies the alias structure for this design. Because of the partial aliasing in this design, it is difficult to interpret the interactions.

Design Expert Output

Alias Matrix

[Est. Terms]	Aliased Terms
[Intercept]	= Intercept - BC - BD - CD
[A]	= A - 0.5 * BC - 0.5 * BD - 0.5 * CD
[B]	= B - 0.5 * AC - 0.5 * AD

[D2]	= D2 + 0.5 * AB - 0.5 * AC + BC

12-7 Consider the connector pull-off force experiment shown in Table 12-2. Show how an experiment can be designed for this problem that will allow a full quadratic model to be fit in the controllable variables along all main effects of the noise variables and their interactions with the controllable variables. How many runs will be required in this design? How does this compare with the design in Table 12-2?

There are several designs that can be employed to achieve the requirements stated above. Below is a small central composite design with the axial points removed for the noise variables. Five center points are also included which brings the total runs to 35. As shown in the alias analysis, the full quadratic model for the controllable variables is achieved.

The "Model F-value" of 2.94 implies the model is not significant relative to the noise. There is a 38.15 % chance that a "Model F-value" this large could occur due to noise.						
Std. Dev.	0.80		R-Squared	0.8545		
Mean	5.25		Adj R-Squared	0.5634		
C.V.	15.26		Pred R-Squared	-1.3284		
PRESS	10.28		Adeq Precision	3.954		
Factor	Coefficient Estimate	DF	Standard Error	95% CI Low	95% CI High	VIF
Intercept	5.25	1	0.40	0.16	10.34	
A-Concentration	-0.66	1	0.40	-5.75	4.43	1.00
B-Stir Rate	0.71	1	0.40	-4.38	5.81	1.00
Final Equation in Terms of Coded Factors:						
Ln(Variance) = +5.25 -0.66 * A +0.71 * B						
Final Equation in Terms of Actual Factors:						
Ln(Variance) = +5.25185 -0.65945 * Concentration +0.71311 * Stir Rate						

The following is a contour plot of the variance model in the untransformed form:

- (c) Find operating conditions that result in the mean filtration rate response exceeding 75 with minimum variance.

The overlay plot shown below identifies the region required by the process:

- (d) Compare your results with those from Example 12-1 which used the transmission of error approach. How similar are the two answers.

The results are very similar. Both require the Concentration to be held at the high level while the stirring rate is held near the middle.

12-10 In an article ("Let's All Beware the Latin Square," *Quality Engineering*, Vol. 1, 1989, pp. 453-465) J.S. Hunter illustrates some of the problems associated with 3^{k-p} fractional factorial designs. Factor A

is the amount of ethanol added to a standard fuel and factor B represents the air/fuel ratio. The response variable is carbon monoxide (CO) emission in g/m². The design is shown below.

Design			Observations		
A	B	x_1	x_2	y	y
0	0	-1	-1	66	62
1	0	0	-1	78	81
2	0	1	-1	90	94
0	1	-1	0	72	67
1	1	0	0	80	81
2	1	1	0	75	78
0	2	-1	1	68	66
1	2	0	1	66	69
2	2	1	1	60	58

Notice that we have used the notation system of 0, 1, and 2 to represent the low, medium, and high levels for the factors. We have also used a “geometric notation” of -1, 0, and 1. Each run in the design is replicated twice.

- (a) Verify that the second-order model

$$\hat{y} = 78.5 + 4.5x_1 - 7.0x_2 - 4.5x_1^2 - 4.0x_2^2 - 9.0x_1x_2$$

is a reasonable model for this experiment. Sketch the CO concentration contours in the x_1, x_2 space.

In the computer output that follows, the “coded factors” model is in the -1, 0, +1 scale.

-7.00 * B
-4.50 * A ²
-4.00 * B ²
-9.00 * A * B

- (b) Now suppose that instead of only two factors, we had used *four* factors in a 3^{4-2} fractional factorial design and obtained *exactly* the same data in part (a). The design would be as follows:

Design				Observations					
A	B	C	D	x_1	x_2	x_3	x_4	y	y
0	0	0	0	-1	-1	-1	-1	66	62
1	0	1	1	0	-1	0	0	78	81
2	0	2	2	+1	-1	+1	+1	90	94
0	1	2	1	-1	0	+1	0	72	67
1	1	0	2	0	0	-1	+1	80	81
2	1	1	0	+1	0	0	-1	75	78
0	2	1	2	-1	+1	0	+1	68	66
1	2	2	0	0	+1	+1	-1	66	69
2	2	0	1	+1	+1	-1	0	60	58

- (c) The design in part (b) allows the model

$$y = \beta_0 + \sum_{i=1}^4 \beta_i x_i + \sum_{i=1}^4 \beta_{ii} x_i^2 + \varepsilon$$

to be fitted. Suppose that the *true* model is

$$y = \beta_0 + \sum_{i=1}^4 \beta_i x_i + \sum_{i=1}^4 \beta_{ii} x_i^2 + \sum_{i < j} \beta_{ij} x_i x_j + \varepsilon$$

Show that if $\hat{\beta}_j$ represents the least squares estimates of the coefficients in the fitted model, then

$$\begin{aligned} E(\hat{\beta}_0) &= \beta_0 - \beta_{13} - \beta_{14} - \beta_{34} \\ E(\hat{\beta}_1) &= \beta_1 - (\beta_{23} + \beta_{24})/2 \\ E(\hat{\beta}_2) &= \beta_2 - (\beta_{13} + \beta_{14} + \beta_{34})/2 \\ E(\hat{\beta}_3) &= \beta_3 - (\beta_{12} + \beta_{24})/2 \\ E(\hat{\beta}_4) &= \beta_4 - (\beta_{12} + \beta_{23})/2 \\ E(\hat{\beta}_{11}) &= \beta_{11} - (\beta_{23} - \beta_{24})/2 \\ E(\hat{\beta}_{22}) &= \beta_{22} + (\beta_{13} + \beta_{14} + \beta_{34})/2 \\ E(\hat{\beta}_{33}) &= \beta_{33} - (\beta_{24} - \beta_{12})/2 + \beta_{14} \\ E(\hat{\beta}_{44}) &= \beta_{44} - (\beta_{12} - \beta_{23})/2 + \beta_{13} \end{aligned}$$

Does this help explain the strong effects for factors *C* and *D* observed graphically in part (b)?

$$\text{Let } \mathbf{X}_1 = \begin{bmatrix} \beta_0 & \beta_1 & \beta_2 & \beta_3 & \beta_4 & \beta_{11} & \beta_{22} & \beta_{33} & \beta_{44} \\ 1 & -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ 1 & 0 & -1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 1 & 1 & -1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & -1 & 1 & 0 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 & -1 & 1 & 0 & 0 & 1 \\ 1 & -1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & -1 & -1 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 \end{bmatrix} \quad \text{and } \mathbf{X}_2 = \begin{bmatrix} \beta_{12} & \beta_{13} & \beta_{14} & \beta_{23} & \beta_{24} & \beta_{34} \\ 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 1 & 1 & -1 & -1 & 1 \\ 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ -1 & 0 & -1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & -1 & -1 \\ 1 & -1 & 0 & -1 & 0 & 0 \end{bmatrix}$$

$$\text{Then, } \mathbf{A} = (\mathbf{X}_1' \mathbf{X}_1)^{-1} \mathbf{X}_1' \mathbf{X}_2 = \mathbf{A} = \begin{bmatrix} 0 & -1 & -1 & 0 & 0 & -1 \\ 0 & 0 & 0 & -1/2 & -1/2 & 0 \\ 0 & -1/2 & -1/2 & 0 & 0 & -1/2 \\ -1/2 & 0 & 0 & 0 & -1/2 & 0 \\ -1/2 & 0 & 0 & -1/2 & 0 & 0 \\ 0 & 0 & 0 & -1/2 & 1/2 & 0 \\ 0 & 1/2 & 1/2 & 0 & 0 & 1/2 \\ 1/2 & 0 & 1 & 0 & -1/2 & 0 \\ -1/2 & 1 & 0 & 1/2 & 0 & 0 \end{bmatrix}$$

 \end{aligned}$$

12-11 An experiment has been run in a process that applies a coating material to a wafer. Each run in the experiment produced a wafer, and the coating thickness was measured several times at different locations on the wafer. Then the mean y_1 , and standard deviation y_2 of the thickness measurement was obtained. The data [adapted from Box and Draper (1987)] are shown in the table below.

Run	Speed	Pressure	Distance	Mean (y_1)	Std Dev (y_2)

- (a) What type of design did the experimenters use? Is this a good choice of design for fitting a quadratic model?

The design is a 3^3 . A better choice would be a 2^3 central composite design. The CCD gives more information over the design region with fewer points.

- (b) Build models of both responses.

The model for the mean is developed as follows:

Design Expert Output

Response:	Mean

The following contour plots graphically represent the two models:

- (c) Find a set of optimum conditions that result in the mean as large as possible with the standard deviation less than 60.

The overlay plot identifies a region that meets the criteria of the mean as large as possible with the standard deviation less than 60. The optimum conditions in coded terms are approximately Speed = 1.0, Pressure = 0.75 and Distance = 0.25.

12-12 Suppose that there are four controllable variables and two noise variables. It is necessary to estimate the main effects and two-factor interactions of all of the controllable variables, the main effects of the noise variables, and the two-factor interactions between all controllable and noise factors. If all factors are at two levels, what is the minimum number of runs that can be used to estimate all of the model parameters using a combined array design? Use a D-optimal algorithm to find a design.

Twenty-one runs are required for the model, with five additional runs for lack of fit, and five as replicates for a total of 31 runs as follows.

Std	A	B	C	D	E	F
1	+1	+1	-1	+1	+1	+1

12-13 Suppose that there are four controllable variables and two noise variables. It is necessary to fit a complete quadratic model in the controllable variables, the main effects of the noise variables, and the two-factor interactions between all controllable and noise factors. Set up a combined array design for this by modifying a central composite design.

The following design is a half fraction central composite design with the axial points removed from the noise factors. The total number of runs is forty-eight which includes eight center points.

12-14 Reconsider the situation in Problem 12-13. Could a modified small composite design be used for this problem? Are there any disadvantages associated with the use of the small composite design?

The axial points for the noise factors were removed in following small central composite design. Five center points are included. The small central composite design does have aliasing with noise factor E aliased with the AD interaction and noise factor F aliased with the BC interaction. These aliases are corrected by leaving the axial points for the noise factors in the design.

12-16 An experiment was run in a wave soldering process. There are five controllable variables and three noise variables. The response variable is the number of solder defects per million opportunities. The experimental design employed was the crossed array shown below.

					Outer Array				
					F	-1	1	1	-1
					G	-1	1	-1	1
A	B	C	D	E	H	-1	-1	1	1

1	1	1	-1	-1	194	197	193	275
1	1	-1	1	1	136	136	132	136
1	-1	1	-1	1	185	261	264	264
1	-1	-1	1	-1	47	125	127	42
-1	1	1	1	-1	295	216	204	293
-1	1	-1	-1	1	234	159	231	157
-1	-1	1	1	1	328	326	247	322
-1	-1	-1	-1	-1	186	187	105	104

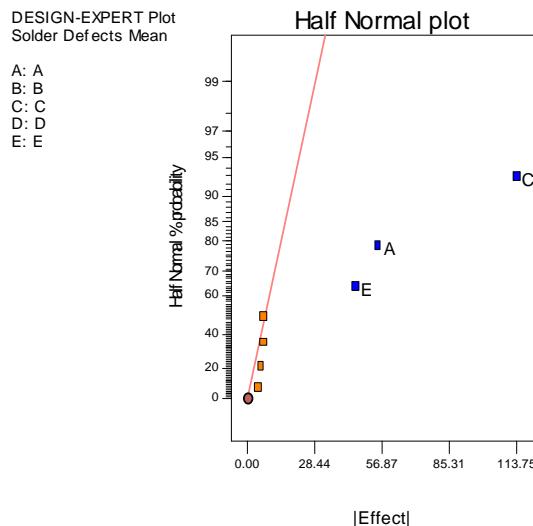

(a) What types of designs were used for the inner and outer arrays?

The inner array is a 2^{5-2} fractional factorial design with a defining relation of $I = -ACD = -BCE = ABDE$. The outer array is a 2^{3-1} fractional factorial design with a defining relation of $I = -FGH$.

(b) Develop models for the mean and variance of solder defects. What set of operating conditions would you recommend?

A	B	C	D	E	\bar{y}	s^2
1	1	1	-1	-1	214.75	1616.25
1	1	-1	1	1	135.00	4.00
1	-1	1	-1	1	243.50	1523.00
1	-1	-1	1	-1	85.25	2218.92
-1	1	1	1	-1	252.00	2376.67
-1	1	-1	-1	1	195.25	1852.25
-1	-1	1	1	1	305.75	1540.25
-1	-1	-1	-1	-1	145.50	2241.67

The following analysis identifies factors A, C, and E as being significant for the solder defects mean model.

Design Expert Output

Response: Solder Defects Mean						
ANOVA for Selected Factorial Model						
Analysis of variance table [Partial sum of squares]						
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F	
Model	36068.63	3	12022.88	194.31	<0.0001	significant
A	6050.00	1	6050.00	97.78	0.0006	

C	25878.13	I	25878.13	418.23	< 0.0001
E	4140.50	I	4140.50	66.92	0.0012
Residual	247.50	4	61.88		
Cor Total	36316.13	7			

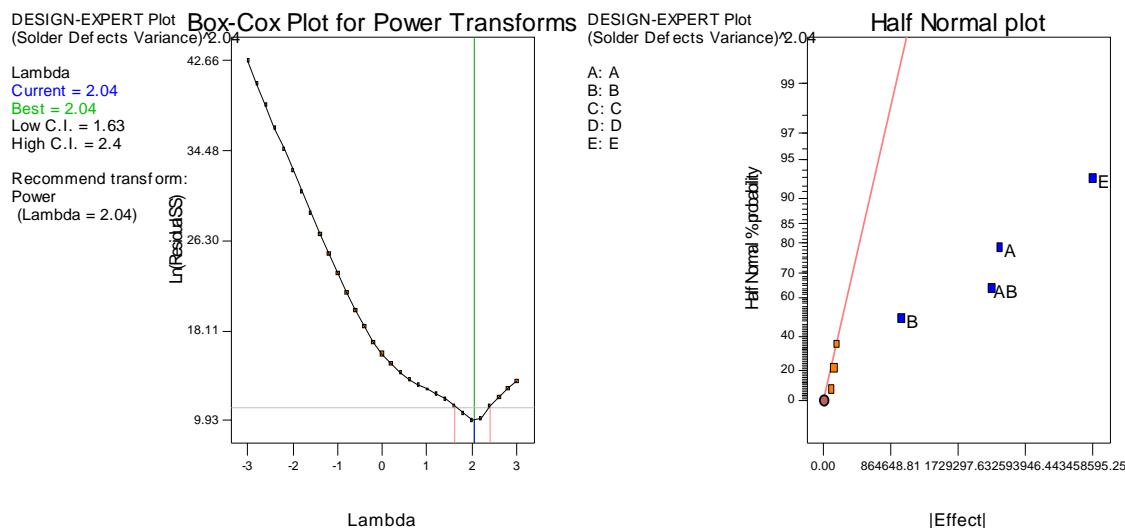

The "Model F-value" of 194.31 implies the model is not significant relative to the noise. There is a 0.01 % chance that a "Model F-value" this large could occur due to noise.

Std. Dev.	7.87	R-Squared	0.9932
Mean	197.13	Adj R-Squared	0.9881
C.V.	3.99	Pred R-Squared	0.9727
PRESS	990.00	Adeq Precision	38.519

Final Equation in Terms of Coded Factors:

$$\begin{aligned} \text{Solder Defects Mean} = \\ +197.13 \\ -27.50 * A \\ +56.88 * C \\ +22.75 * E \end{aligned}$$

Although the natural log transformation is often utilized for variance response, a power transformation actually performed better for this problem per the Box-Cox plot below. The analysis for the solder defect variance follows.

Design Expert Output

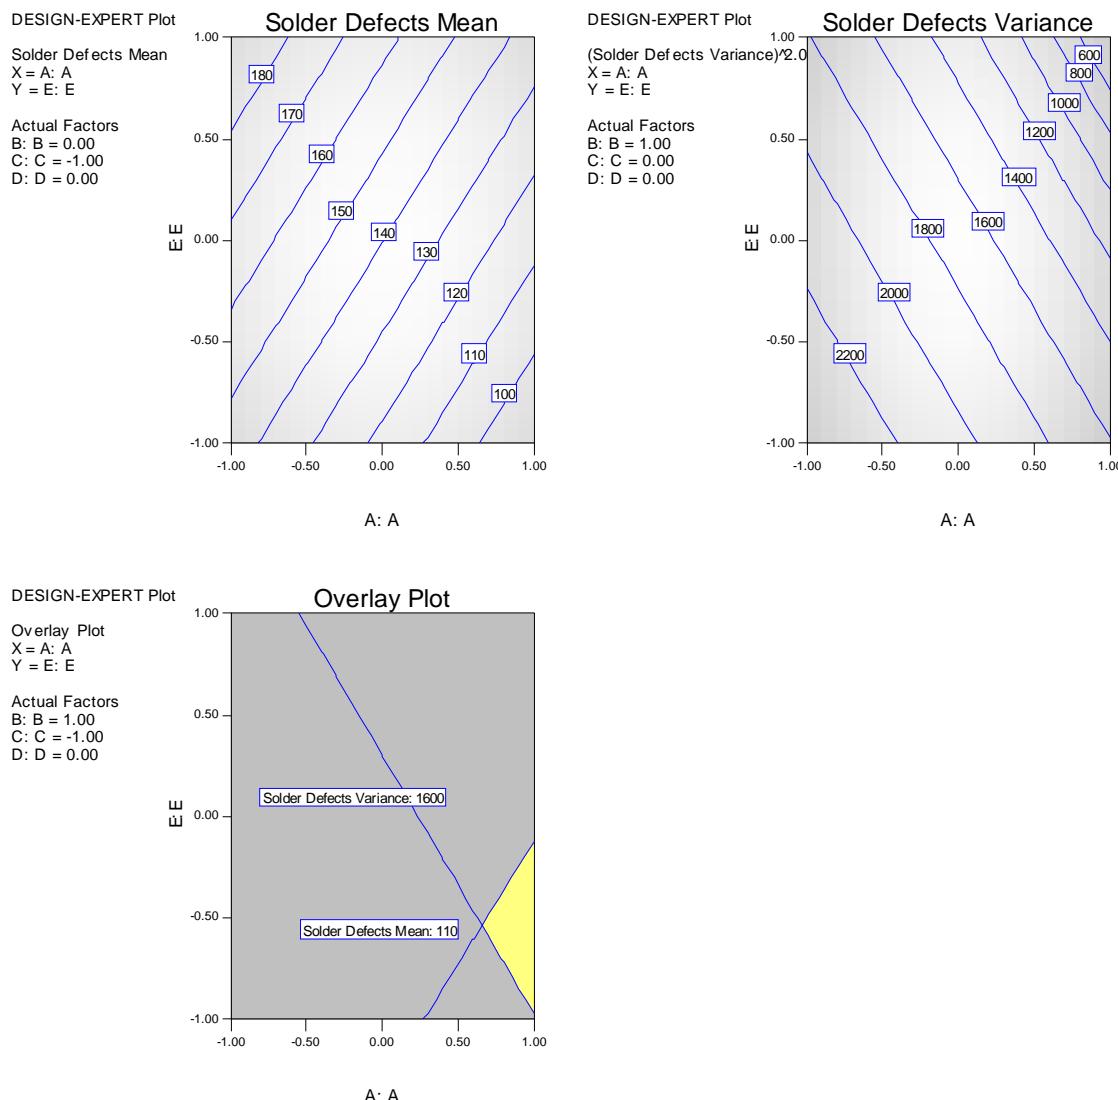

Response: Solder Defects Variance		Transform:	Power	Lambda:	2.04	Constant: 0
ANOVA for Selected Factorial Model						
Analysis of variance table [Partial sum of squares]						
Source	Sum of Squares	DF	Mean Square	F Value	Prob > F

Chapter 13

Experiments with Random Factors

Solutions

13-1 A textile mill has a large number of looms. Each loom is supposed to provide the same output of cloth per minute. To investigate this assumption, five looms are chosen at random and their output is noted at different times. The following data are obtained:

Loom	Output (lb/min)				
1	14.0	14.1	14.2	14.0	14.1
2	13.9	13.8	13.9	14.0	14.0
3	14.1	14.2	14.1	14.0	13.9
4	13.6	13.8	14.0	13.9	13.7
5	13.8	13.6	13.9	13.8	14.0

- (a) Explain why this is a random effects experiment. Are the looms equal in output? Use $\alpha = 0.05$.

The looms used in the experiment are a random sample of all the looms in the manufacturing area. The following is the analysis of variance for the data:

Minitab Output

ANOVA: Output versus Loom

Factor	Type	Levels	Values				
Loom	random	5	1	2	3	4	5
Analysis of Variance for Output							
Source	DF	SS	MS	F	P		
Loom	4	0.34160	0.08540	5.77	0.003		
Error	20	0.29600	0.01480				
Total	24	0.63760					
Source Variance Error Expected Mean Square for Each Term component term (using restricted model)							
1 Loom	0.01412	2	(2) + 5(1)				
2 Error	0.01480		(2)				

- (b) Estimate the variability between looms.

$$\hat{\sigma}_\tau^2 = \frac{MS_{Model} - MS_E}{n} = \frac{0.0854 - 0.0148}{5} = 0.01412$$

- (c) Estimate the experimental error variance.

$$\hat{\sigma}^2 = MS_E = 0.0148$$

- (d) Find a 95 percent confidence interval for $\sigma_\tau^2 / (\sigma_\tau^2 + \sigma^2)$.

$$L = \frac{1}{n} \left[\frac{MS_{Model}}{MS_E} \frac{1}{F_{a/2, a-1, n-a}} - 1 \right] = \frac{1}{5} \left[\frac{0.08540}{0.01480} \times \frac{1}{3.51} - 1 \right] = 0.1288$$

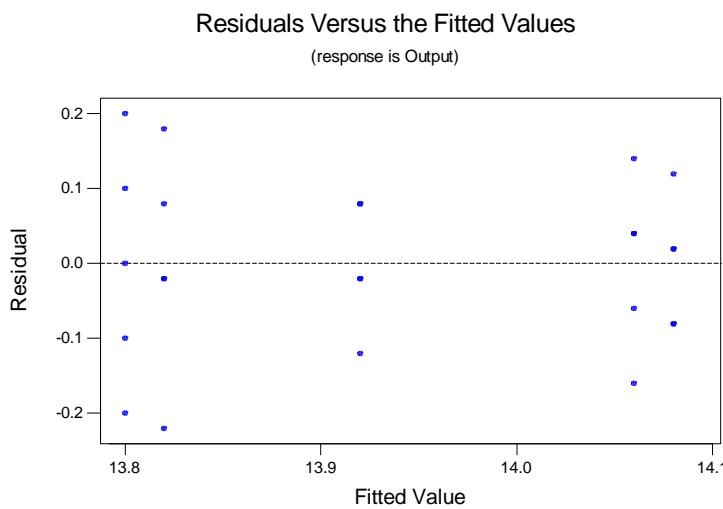

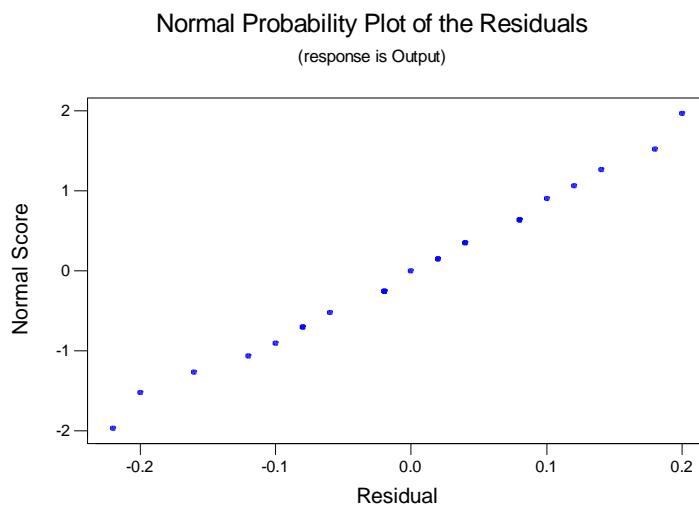

$$U = \frac{1}{n} \left[\frac{MS_{Model}}{MS_E} \frac{1}{F_{1-\alpha/2, a-1, n-a}} - 1 \right] = \frac{1}{5} \left[\frac{0.08540}{0.01480} \times 8.56 - 1 \right] = 9.6787$$

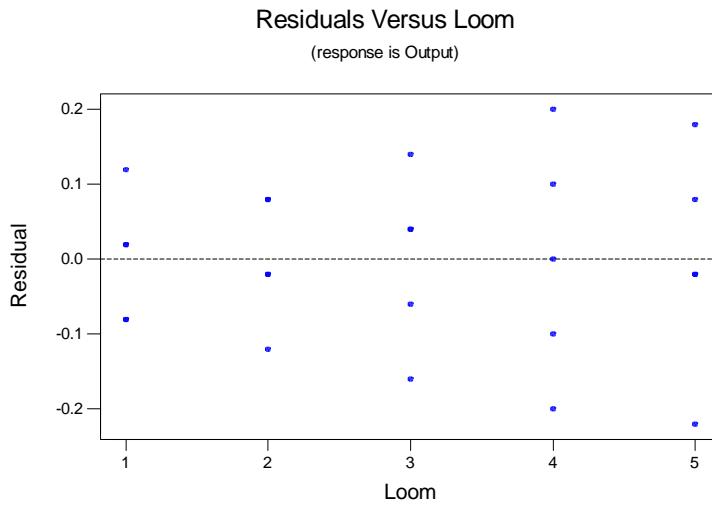

$$\frac{L}{L+1} \leq \frac{\sigma_\tau^2}{\sigma_\tau^2 + \sigma^2} \leq \frac{U}{U+1}$$

$$0.1141 \leq \frac{\sigma_\tau^2}{\sigma_\tau^2 + \sigma^2} \leq 0.9064$$

- (e) Analyze the residuals from this experiment. Do you think that the analysis of variance assumptions are satisfied?

There is nothing unusual about the residual plots; therefore, the analysis of variance assumptions are satisfied.

13-2 A manufacturer suspects that the batches of raw material furnished by her supplier differ significantly in calcium content. There are a large number of batches currently in the warehouse. Five of these are randomly selected for study. A chemist makes five determinations on each batch and obtains the following data:

Batch 1	Batch 2	Batch 3	Batch 4	Batch 5
23.46	23.59	23.51	23.28	23.29
23.48	23.46	23.64	23.40	23.46
23.56	23.42	23.46	23.37	23.37
23.39	23.49	23.52	23.46	23.32
23.40	23.50	23.49	23.39	23.38

- (a) Is there significant variation in calcium content from batch to batch? Use $\alpha = 0.05$.

Yes, as shown in the Minitab Output below, there is a difference.

Minitab Output

ANOVA: Calcium versus Batch

Factor	Type	Levels	Values			
Batch	random	5	1	2	3	4
Analysis of Variance for Calcium						
Source	DF	SS	MS	F	P	
Batch	4	0.096976	0.024244	5.54	0.004	
Error	20	0.087600	0.004380			
Total	24	0.184576				
Source Variance Error Expected Mean Square for Each Term component term (using restricted model)						
1 Batch	0.00397	2	(2) + 5(1)			
2 Error	0.00438		(2)			

- (b) Estimate the components of variance.

$$\hat{\sigma}_\tau^2 = \frac{MS_{Model} - MS_E}{n} = \frac{0.024244 - 0.004380}{5} = 0.00397$$

$$\hat{\sigma}^2 = MS_E = 0.004380$$

- (c) Find a 95 percent confidence interval for $\sigma_\tau^2 / (\sigma_\tau^2 + \sigma^2)$.

$$L = \frac{1}{n} \left[\frac{MS_{Model}}{MS_E} \frac{1}{F_{\alpha/2, a-1, n-a}} - 1 \right] = 0.1154$$

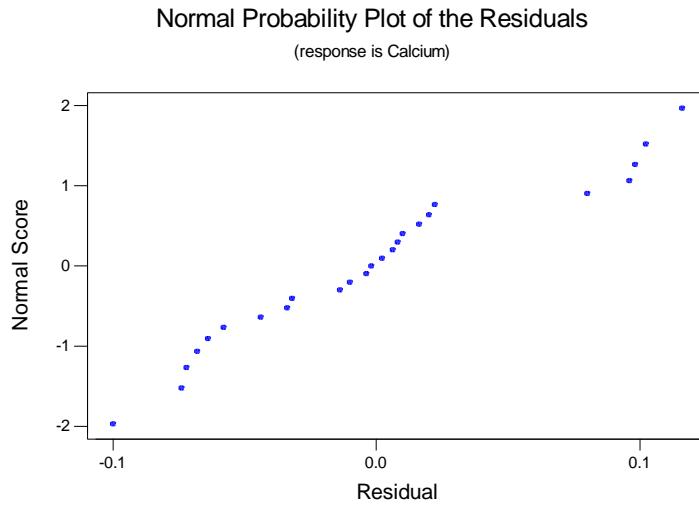

$$U = \frac{1}{n} \left[\frac{MS_{Model}}{MS_E} \frac{1}{F_{1-\alpha/2, a-1, n-a}} - 1 \right] = 9.276$$

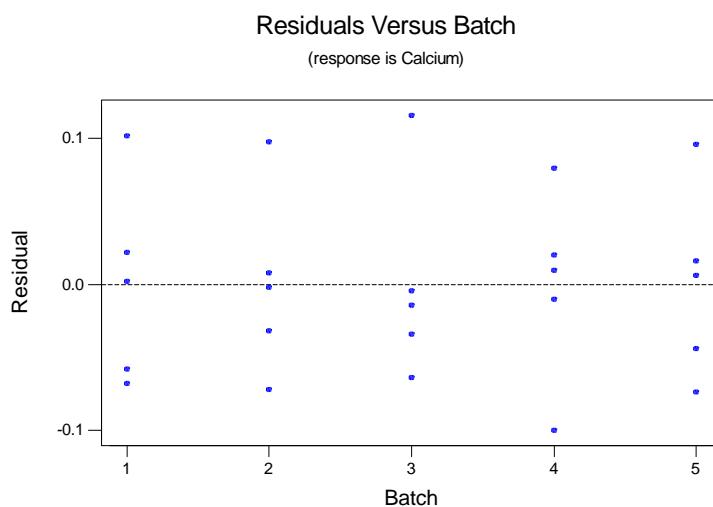

$$\frac{L}{L+1} \leq \frac{\sigma_\tau^2}{\sigma_\tau^2 + \sigma^2} \leq \frac{U}{U+1}$$

$$0.1035 \leq \frac{\sigma_\tau^2}{\sigma_\tau^2 + \sigma^2} \leq 0.9027$$

- (d) Analyze the residuals from this experiment. Are the basic analysis of variance assumptions satisfied?

There are five residuals that stand out in the normal probability plot. From the Residual vs. Batch plot, we see that one point per batch appears to stand out. A natural log transformation was applied to the data but did not change the results of the residual analysis. Further investigation should probably be performed to determine if these points are outliers.

13-3 Several ovens in a metal working shop are used to heat metal specimens. All the ovens are supposed to operate at the same temperature, although it is suspected that this may not be true. Three ovens are selected at random and their temperatures on successive heats are noted. The data collected are as follows:

Oven	Temperature					
1	491.50	498.30	498.10	493.50	493.60	
2	488.50	484.65	479.90	477.35		
3	490.10	484.80	488.25	473.00	471.85	478.65

- (a) Is there significant variation in temperature between ovens? Use $\alpha = 0.05$.

The analysis of variance shown below identifies significant variation in temperature between the ovens.

Minitab Output

General Linear Model: Temperature versus Oven

Factor	Type	Levels	Values
--------	------	--------	--------

1 Oven	12.00	34.48	(2)		
Variance Components, using Adjusted SS					
Source	Estimated Value				
Oven	53.27				
Error	34.48				

(b) Estimate the components of variance.

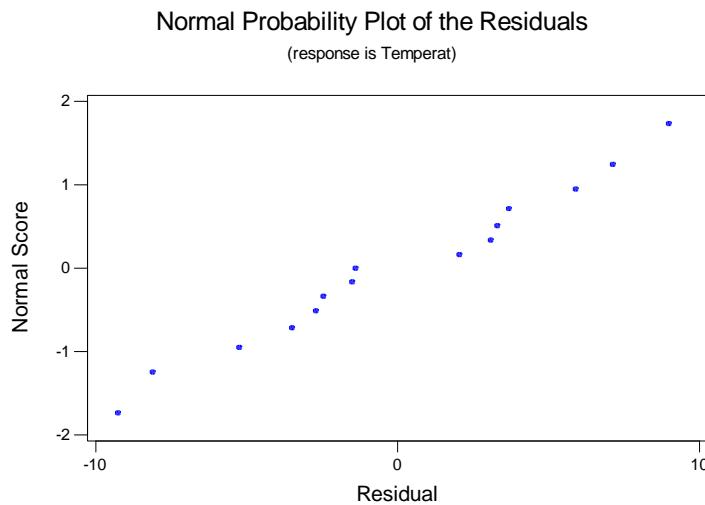

$$n_0 = \frac{1}{a-1} \left[\sum n_i - \frac{\sum n_i^2}{\sum n_i} \right] = \frac{1}{2} \left[15 - \frac{25+16+36}{15} \right] = 4.93$$

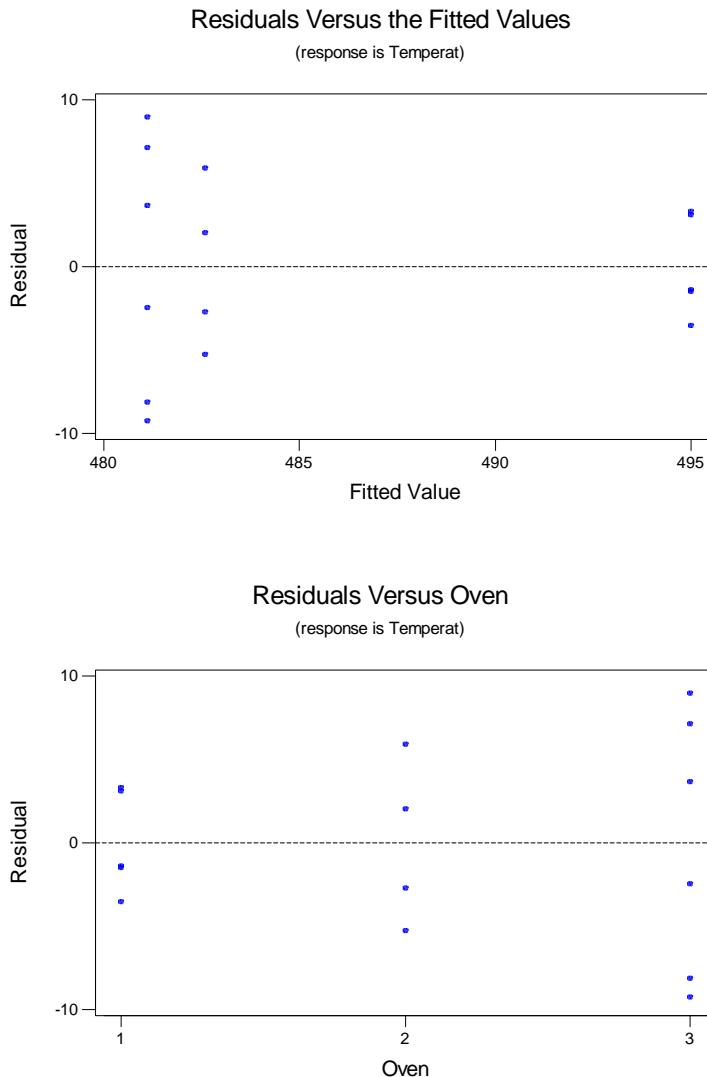

$$\hat{\sigma}_\tau^2 = \frac{MS_{Model} - MS_E}{n} = \frac{297.27 - 34.48}{4.93} = 53.30$$

$$\hat{\sigma}^2 = MS_E = 34.48$$

(c) Analyze the residuals from this experiment. Draw conclusions about model adequacy.

There is a funnel shaped appearance in the plot of residuals versus predicted value indicating a possible non-constant variance. There is also some indication of non-constant variance in the plot of residuals versus oven. The inequality of variance problem is not severe.

13-4 An article in the *Journal of the Electrochemical Society* (Vol. 139, No. 2, 1992, pp. 524-532) describes an experiment to investigate the low-pressure vapor deposition of polysilicon. The experiment was carried out in a large-capacity reactor at Sematech in Austin, Texas. The reactor has several wafer positions, and four of these positions are selected at random. The response variable is film thickness uniformity. Three replicates of the experiments were run, and the data are as follows:

Wafer Position	Uniformity		
1	2.76	5.67	4.49
2	1.43	1.70	2.19
3	2.34	1.97	1.47
4	0.94	1.36	1.65

- (a) Is there a difference in the wafer positions? Use $\alpha = 0.05$.

Yes, there is a difference.

Minitab Output

ANOVA: Uniformity versus Wafer Position

Factor	Type	Levels	Values
Wafer Po	fixed	4	1 2 3 4

Analysis of Variance for Uniformi

Source	DF	SS	MS	F	P
Wafer Po	3	16.2198	5.4066	8.29	0.008
Error	8	5.2175	0.6522		
Total	11	21.4373			

Source	Variance Component	Error Term	Expected Mean Square for Each Term
1 Wafer Po	2	(2)	+ 3Q[1]
2 Error	0.6522	(2)	

- (b) Estimate the variability due to wafer positions.

$$\hat{\sigma}_\tau^2 = \frac{MS_{Treatment} - MS_E}{n}$$

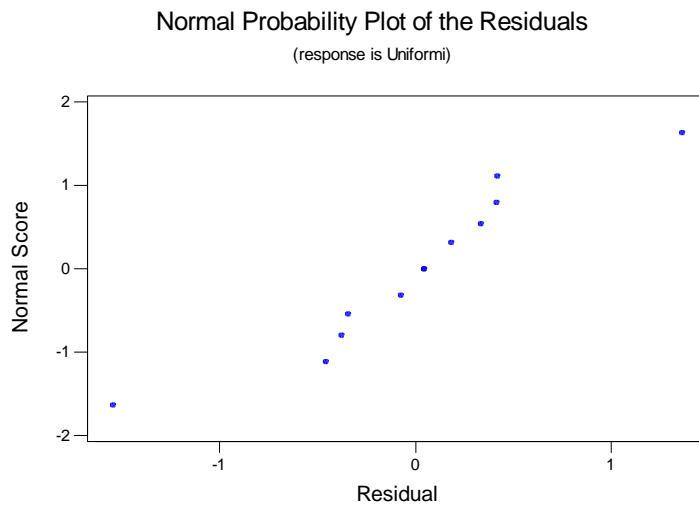

$$\hat{\sigma}_\tau^2 = \frac{5.4066 - 0.6522}{3} = 1.5844$$

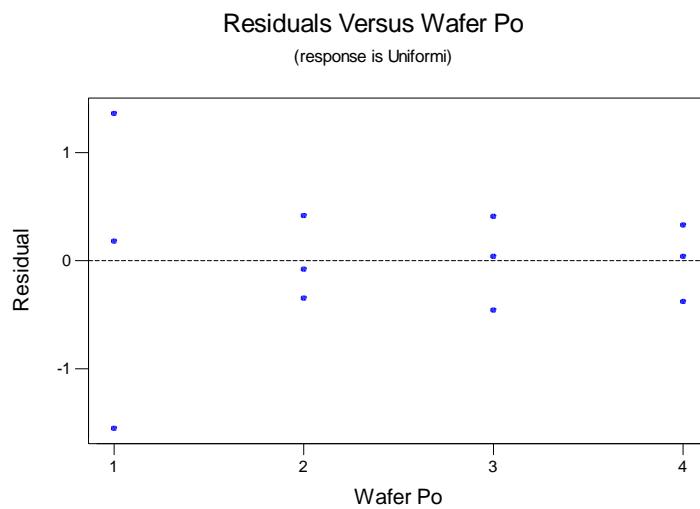

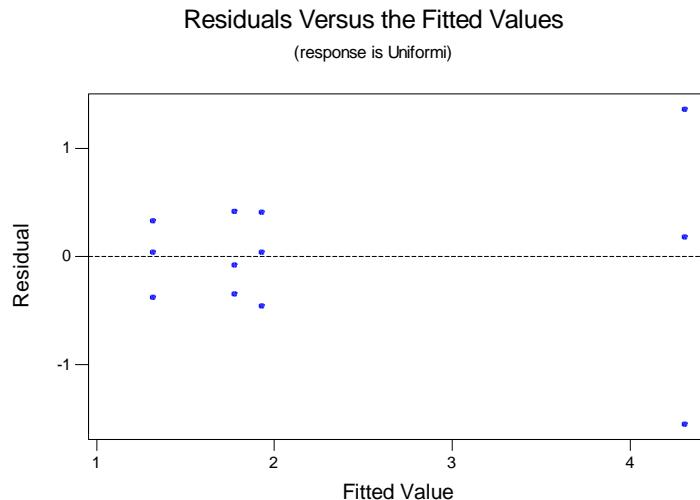

- (c) Estimate the random error component.

$$\hat{\sigma}^2 = 0.6522$$

- (d) Analyze the residuals from this experiment and comment on model adequacy.

Variability in film thickness seems to depend on wafer position. These observations also show up as outliers on the normal probability plot. Wafer position number 1 appears to have greater variation in uniformity than the other positions.

13-5 Consider the vapor deposition experiment described in Problem 13-4.

- (a) Estimate the total variability in the uniformity response.

$$\hat{\sigma}_\tau^2 + \hat{\sigma}^2 = 1.5848 + 0.6522 = 2.2370$$

- (b) How much of the total variability in the uniformity response is due to the difference between positions in the reactor?

$$\frac{\hat{\sigma}_\tau^2}{\hat{\sigma}^2 + \hat{\sigma}_\tau^2} = \frac{1.5848}{2.2370} = 0.70845$$

- (c) To what level could the variability in the uniformity response be reduced, if the position-to-position variability in the reactor could be eliminated? Do you believe this is a significant reduction?

The variability would be reduced from 2.2370 to $\hat{\sigma}^2 = 0.6522$ which is a reduction of approximately:

$$\frac{2.2370 - 0.6522}{2.2370} = 71\%$$

13-6 An article in the *Journal of Quality Technology* (Vol. 13, No. 2, 1981, pp. 111-114) describes an experiment that investigates the effects of four bleaching chemicals on pulp brightness. These four chemicals were selected at random from a large population of potential bleaching agents. The data are as follows:

Chemical	Pulp Brightness				
1	77.199	74.466	92.746	76.208	82.876
2	80.522	79.306	81.914	80.346	73.385
3	79.417	78.017	91.596	80.802	80.626
4	78.001	78.358	77.544	77.364	77.386

- (a) Is there a difference in the chemical types? Use $\alpha = 0.05$.

The computer output shows that the null hypothesis cannot be rejected. Therefore, there is no evidence that there is a difference in chemical types.

Minitab Output

ANOVA: Brightness versus Chemical

Factor	Type	Levels	Values			
Chemical	random	4	1	2	3	4
Analysis of Variance for Brightne						
Source	DF	SS	MS	F	P	
Chemical	3	53.98	17.99	0.75	0.538	
Error	16	383.99	24.00			
Total	19	437.97				
Source Variance Error Expected Mean Square for Each Term component term (using restricted model)						
1 Chemical	-1.201	2	(2) + 5(1)			
2 Error	23.999		(2)			

- (b) Estimate the variability due to chemical types.

$$\hat{\sigma}_{\tau}^2 = \frac{MS_{Treatment} - MS_E}{n}$$

$$\hat{\sigma}_{\tau}^2 = \frac{17.994 - 23.999}{5} = -1.201$$

which agrees with the Minitab output.

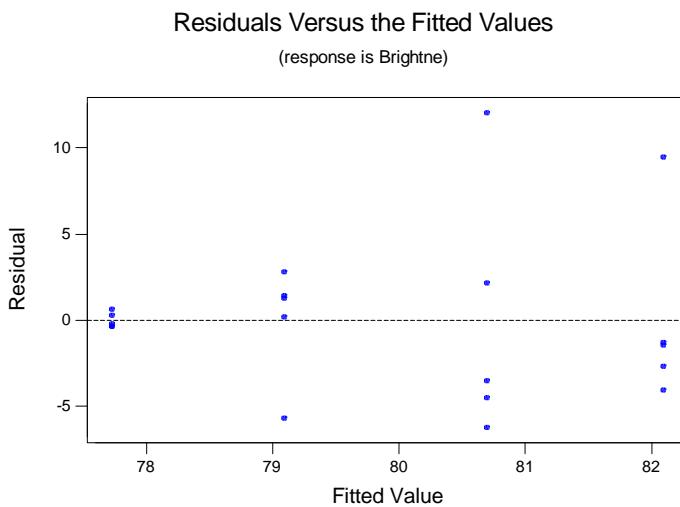

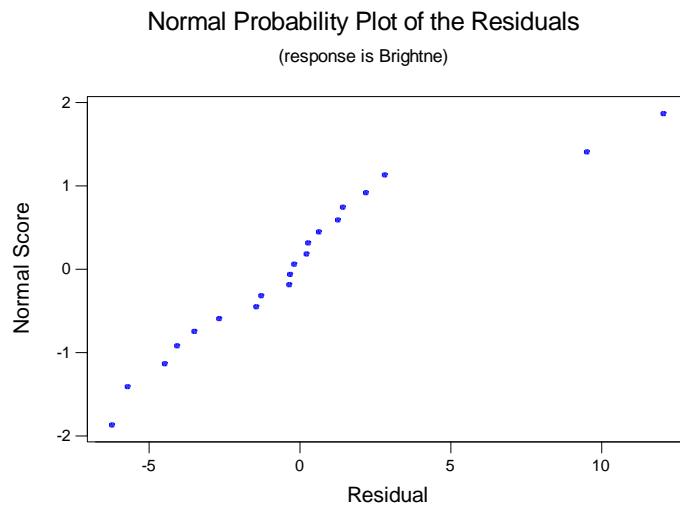

Because the variance component cannot be negative, this likely means that the variability due to chemical types is zero.

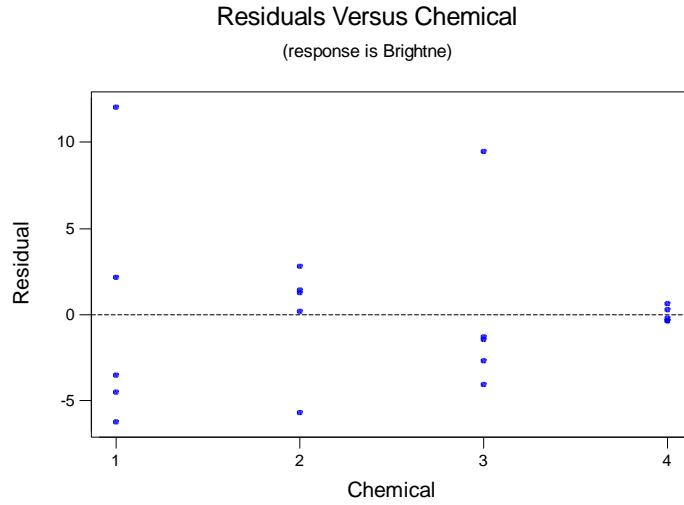

- (c) Estimate the variability due to random error.

$$\hat{\sigma}^2 = 23.999$$

- (d) Analyze the residuals from this experiment and comment on model adequacy.

Two data points appear to be outliers in the normal probability plot of effects. These outliers belong to chemical types 1 and 3 and should be investigated. There seems to be much less variability in brightness with chemical type 4.

13-7 Consider the one-way balanced, random effects method. Develop a procedure for finding a $100(1-\alpha)$ percent confidence interval for $\sigma^2 / (\sigma_\tau^2 + \sigma^2)$.

$$\begin{aligned} \text{We know that } P\left[L \leq \frac{\sigma_\tau^2}{\sigma^2} \leq U\right] &= 1 - \alpha \\ P\left[L + 1 \leq \frac{\sigma_\tau^2}{\sigma^2} + \frac{\sigma^2}{\sigma^2} \leq U + 1\right] &= 1 - \alpha \\ P\left[L + 1 \leq \frac{\sigma_\tau^2 + \sigma^2}{\sigma^2} \leq U + 1\right] &= 1 - \alpha \\ P\left[\frac{L}{1+L} \geq \frac{\sigma^2}{\sigma_\tau^2 + \sigma^2} \geq \frac{U}{1+U}\right] &= 1 - \alpha \end{aligned}$$

13-8 Refer to Problem 13-1.

(a) What is the probability of accepting H_0 if σ_τ^2 is four times the error variance σ^2 ?

$$\lambda = \sqrt{1 + \frac{n\sigma_\tau^2}{\sigma^2}} = \sqrt{1 + \frac{5(4\sigma^2)}{\sigma^2}} = \sqrt{21} = 4.6$$

$$v_1 = a - 1 = 4 \quad v_2 = N - a = 25 - 5 = 20 \quad \beta \approx 0.035, \text{ from the OC curve.}$$

(b) If the difference between looms is large enough to increase the standard deviation of an observation by 20 percent, we wish to detect this with a probability of at least 0.80. What sample size should be used?

$$v_1 = a - 1 = 4 \quad v_2 = N - a = 25 - 5 = 20 \quad \alpha = 0.05 \quad P(\text{accept}) \leq 0.2$$

$$\lambda = \sqrt{1 + n[(1 + 0.01P)^2 - 1]} = \sqrt{1 + n[(1 + 0.01(20))^2 - 1]} = \sqrt{1 + 0.44n}$$

Trial and Error yields:

n	v_2	λ	P(accept)
5	20	1.79	0.6
10	45	2.32	0.3
14	65	2.67	0.2

Choose $n \geq 14$, therefore $N \geq 70$

- 13-9** An experiment was performed to investigate the capability of a measurement system. Ten parts were randomly selected, and two randomly selected operators measured each part three times. The tests were made in random order, and the data below resulted.

Part Number	Operator 1			Operator 2		
	Measurements			Measurements

$$\hat{\sigma}_{\tau\beta}^2 = \frac{MS_{AB} - MS_E}{n} \quad \hat{\sigma}_{\tau\beta}^2 = \frac{2.70 - 0.51}{3} = 0.73$$

$$\hat{\sigma}_\beta^2 = \frac{MS_B - MS_E}{an} \quad \hat{\sigma}_\beta^2 = \frac{437.33 - 0.51}{3(3)} = 48.54$$

These results agree with the Minitab output.

13-16 In problem 5-6, suppose that there are only four machines of interest, but the operators were selected at random.

(a) What type of model is appropriate?

A mixed model is appropriate.

(b) Perform the analysis and estimate the model components.

The following analysis assumes a restricted model:

Minitab Output

ANOVA: Strength versus Operator, Machine						
Factor	Type	Levels	Values	DF	SS	MS
Operator	random	3	1	2	3	
Machine	fixed	4	1	2	3	4
Analysis of Variance for Strength

$$\hat{\sigma}^2 = MS_E \quad \hat{\sigma}^2 = 3.792$$

$$\hat{\sigma}_{\tau\beta}^2 = \frac{MS_{AB} - MS_E}{n} \quad \hat{\sigma}_{\tau\beta}^2 = \frac{7.444 - 3.792}{2} = 1.826$$

$$\hat{\sigma}_\tau^2 = \frac{MS_A - MS_E}{bn} \quad \hat{\sigma}_\tau^2 = \frac{80.167 - 3.792}{4(2)} = 9.547$$

These results agree with the Minitab output.

13-17 By application of the expectation operator, develop the expected mean squares for the two-factor factorial, mixed model. Use the restricted model assumptions. Check your results with the expected mean squares given in Equation 13-23 to see that they agree.

The sums of squares may be written as

$$SS_A = bn \sum_{i=1}^a (\bar{y}_{i..} - \bar{y}_{...})^2, \quad SS_B = an \sum_{j=1}^b (\bar{y}_{.j.} - \bar{y}_{...})^2$$

$$SS_{AB} = n \sum_{i=1}^a \sum_{j=1}^b (\bar{y}_{ij.} - \bar{y}_{i..} - \bar{y}_{.j.} + \bar{y}_{...})^2, \quad SS_E = \sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^n (y_{ijk} - \bar{y}_{...})^2$$

Using the model $y_{ijk} = \mu + \tau_i + \beta_j + (\tau\beta)_{ij} + \varepsilon_{ijk}$, we may find that

$$\begin{aligned}\bar{y}_{i..} &= \mu + \tau_i + (\bar{\varepsilon}\bar{\beta})_{i..} + \bar{\varepsilon}_{i..} \\ \bar{y}_{.j.} &= \mu + \beta_j + \bar{\varepsilon}_{.j.} \\ \bar{y}_{ij.} &= \mu + \tau_i + \beta_j + (\tau\beta)_{ij} + \bar{\varepsilon}_{ij.} \\ \bar{y}_{...} &= \mu + \bar{\beta} + \bar{\varepsilon}_{...}\end{aligned}$$

Using the assumptions for the restricted form of the mixed model, $\tau_i = 0$, $(\tau\beta)_{.j} = 0$, which imply that $(\tau\beta)_{...} = 0$. Substituting these expressions into the sums of squares yields

$$SS_A = bn \sum_{i=1}^a (\tau + (\tau\beta)_{i..} + \bar{\varepsilon}_{i..} - \bar{\varepsilon}_{...})^2$$

$$SS_B = an \sum_{j=1}^b (\beta_j + \bar{\varepsilon}_{.j.} - \bar{\varepsilon}_{...})^2$$

$$SS_{AB} = n \sum_{i=1}^a \sum_{j=1}^b ((\tau\beta)_{ij} - (\tau\beta)_{i..} + \bar{\varepsilon}_{ij.} - \bar{\varepsilon}_{i..} - \bar{\varepsilon}_{.j.} + \bar{\varepsilon}_{...})^2$$

$$SS_E = \sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^n (\varepsilon_{ijk} - \bar{\varepsilon}_{ij.})^2$$

Using the assumption that $E(\varepsilon_{ijk}) = 0$, $V(\varepsilon_{ijk}) = 0$, and $E(\varepsilon_{ijk} \cdot \varepsilon_{i'j'k'}) = 0$, we may divide each sum of squares by its degrees of freedom and take the expectation to produce

$$\begin{aligned}
 E(MS_A) &= \sigma^2 + \left[\frac{bn}{(a-1)} \right] E \sum_{i=1}^a (\tau_i + (\bar{\tau}\bar{\beta})_{\cdot i})^2 \\
 E(MS_B) &= \sigma^2 + \left[\frac{an}{(b-1)} \right] \sum_{j=1}^b \beta_j^2 \\
 E(MS_{AB}) &= \sigma^2 + \left[\frac{n}{(a-1)(b-1)} \right] E \sum_{i=1}^a \sum_{j=1}^b ((\tau\beta)_{ij} - (\bar{\tau}\bar{\beta})_{\cdot i})^2 \\
 E(MS_E) &= \sigma^2
 \end{aligned}$$

Note that $E(MS_B)$ and $E(MS_E)$ are the results given in Table 8-3. We need to simplify $E(MS_A)$ and $E(MS_{AB})$. Consider $E(MS_A)$

$$\begin{aligned}
 E(MS_A) &= \sigma^2 + \frac{bn}{a-1} \left[\sum_{i=1}^a E(\tau_i)^2 + \sum_{i=1}^a E(\tau\beta)_{\cdot i}^2 + (\text{crossproducts} = 0) \right] \\
 E(MS_A) &= \sigma^2 + \frac{bn}{a-1} \left[\sum_{i=1}^a \tau_i^2 + a \left[\frac{(a-1)}{a} \right] \sigma_{\tau\beta}^2 \right] \\
 E(MS_A) &= \sigma^2 + n\sigma_{\tau\beta}^2 + \frac{bn}{a-1} \sum_{i=1}^a \tau_i^2
 \end{aligned}$$

since $(\tau\beta)_{ij}$ is $NID\left(0, \frac{a-1}{a} \sigma_{\tau\beta}^2\right)$. Consider $E(MS_{AB})$

$$\begin{aligned}
 E(MS_{AB}) &= \sigma^2 + \frac{n}{(a-1)(b-1)} \sum_{i=1}^a \sum_{j=1}^b E((\tau\beta)_{ij} - (\bar{\tau}\bar{\beta})_{\cdot i})^2 \\
 E(MS_{AB}) &= \sigma^2 + \frac{n}{(a-1)(b-1)} \sum_{i=1}^a \sum_{j=1}^b \left(\frac{b-1}{b} \right) \left(\frac{a-1}{a} \right) \sigma_{\tau\beta}^2 \\
 E(MS_{AB}) &= \sigma^2 + n\sigma_{\tau\beta}^2
 \end{aligned}$$

Thus $E(MS_A)$ and $E(MS_{AB})$ agree with Equation 13-23..

13-18 Consider the three-factor factorial design in Example 13-6. Propose appropriate test statistics for all main effects and interactions. Repeat for the case where A and B are fixed and C is random.

If all three factors are random there are no exact tests on main effects. We could use the following:

$$\begin{aligned}
 A : F &= \frac{MS_A + MS_{ABC}}{MS_{AB} + MS_{AC}} \\
 B : F &= \frac{MS_B + MS_{ABC}}{MS_{AB} + MS_{BC}} \\
 C : F &= \frac{MS_C + MS_{ABC}}{MS_{AC} + MS_{BC}}
 \end{aligned}$$

If A and B are fixed and C is random, the expected mean squares are (assuming the restricted for m of the model):

Factor	F	F	R	R	
	a	b	c	n	E(MS)
τ_i	0	b	c	n	$\sigma^2 + bn\sigma_{\tau\gamma}^2 + bcn \sum \frac{\tau_i^2}{(a-1)}$
β_j	a	0	c	n	$\sigma^2 + an\sigma_{\beta\gamma}^2 + acn \sum \frac{\beta_j^2}{(b-1)}$
γ_k	a	b	1	n	$\sigma^2 + abn\sigma_{\gamma}^2$
$(\tau\beta)_{ij}$	0	0	c	n	$\sigma^2 + n\sigma_{\tau\beta\gamma}^2 + cn \sum \sum \frac{(\tau\beta)_{ji}^2}{(a-1)(b-1)}$
$(\tau\gamma)_{ik}$	0	b	1	n	$\sigma^2 + bn\sigma_{\tau\gamma}^2$
$(\beta\gamma)_{jk}$	a	0	1	n	$\sigma^2 + an\sigma_{\beta\gamma}^2$
$(\tau\beta\gamma)_{ijk}$	0	0	1	n	$\sigma^2 + n\sigma_{\tau\beta\gamma}^2$
$\varepsilon_{(ijk)l}$	1	1	1	1	σ^2

These are exact tests for all effects.

13-19 Consider the experiment in Example 13-7. Analyze the data for the case where A , B , and C are random.

$(\beta\gamma)_{jk}$	a	1	1	n	$\sigma^2 + an\sigma_{\beta\gamma}^2$
$(\tau\beta\gamma)_{ijk}$	0	1	1	n	$\sigma^2 + n\sigma_{\tau\beta\gamma}^2$
ε_{ijkl}	1	1	1	1	σ^2

13-21 Consider a four-factor factorial experiment where factor A is at a levels, factor B is at b levels, factor C is at c levels, factor D is at d levels, and there are n replicates. Write down the sums of squares, the degrees of freedom, and the expected mean squares for the following cases. Do exact tests exist for all effects? If not, propose test statistics for those effects that cannot be directly tested. Assume the restricted model on all cases. You may use a computer package such as Minitab.

The four factor model is:

$$y_{ijklh} = \mu + \tau_i + \beta_j + \gamma_k + \delta_l + (\tau\beta)_{ij} + (\tau\gamma)_{ik} + (\tau\delta)_{il} + (\beta\gamma)_{jk} + (\beta\delta)_{jl} + (\gamma\delta)_{kl} + (\tau\beta\gamma)_{ijk} + (\tau\beta\delta)_{ijl} + (\beta\gamma\delta)_{jkl} + (\tau\gamma\delta)_{ikl} + (\tau\beta\gamma\delta)_{ijkl} + \varepsilon_{ijklh}$$

To simplify the expected mean square derivations, let capital Latin letters represent the factor effects or

variance components. For example, $A = \frac{bcdn\sum \tau_i^2}{a-1}$, or $B = acdn\sigma_{\beta}^2$.

(a) A, B, C , and D are fixed factors.

Factor	F	F	F	F	R	E(MS)
	a	b	c	d	n	
i	j	k	l	h		
τ_i	0	b	c	d	n	$\sigma^2 + A$

$\varepsilon_{(ijkl)h}$	1	1	1	1	1	σ^2

No exact tests exist on main effects or two-factor interactions involving the fixed factor A . To test the fixed factor A use

$$A:F = \frac{MS_A + MS_{ABC} + MS_{ABD} + MS_{ACD}}{MS_{AB} + MS_{AC} + MS_{AD} + MS_{ABCD}}$$

Random main effects could be tested by, for example: $D:F = \frac{MS_D + MS_{ABCD}}{MS_{ABC} + MS_{ABD}}$

For testing two-factor interactions involving A use: $AB:F = \frac{MS_{AB} + MS_{ABCD}}{MS_{ABC} + MS_{ABD}}$

The results can also be generated in Minitab as follows:

The following calculations agree with the Minitab results:

$$\begin{aligned}
\hat{\sigma}^2 &= MS_E & \hat{\sigma}^2 &= 3.27778 \\
\hat{\sigma}_{\tau\beta\gamma}^2 &= \frac{MS_{ABC} - MS_E}{n} & \hat{\sigma}_{\tau\beta\gamma}^2 &= \frac{11.546296 - 3.277778}{3} = 2.7562 \\
\hat{\sigma}_{\beta\gamma}^2 &= \frac{MS_{BC} - MS_E}{an} & \hat{\sigma}_{\beta\gamma}^2 &= \frac{88.91667 - 3.277778}{2(3)} = 14.27315 \\
\hat{\sigma}_{\tau\gamma}^2 &= \frac{MS_{AC} - MS_E}{bn} & \hat{\sigma}_{\tau\gamma}^2 &= \frac{5.629630 - 3.277778}{3(3)} = 0.26132 \\
\hat{\sigma}_\gamma^2 &= \frac{MS_C - MS_E}{abn} & \hat{\sigma}_\gamma^2 &= \frac{130.66667 - 3.277778}{2(3)(3)} = 7.07716
\end{aligned}$$

13-24 Consider the three-factor model

$$y_{ijk} = \mu + \tau_i + \beta_j + \gamma_k + (\tau\beta)_{ij} + (\beta\gamma)_{jk} + (\tau\gamma)_{ik} + \varepsilon_{ijk}$$

Assuming that all the factors are random, develop the analysis of variance table, including the expected mean squares. Propose appropriate test statistics for all effects.

Source	DF	E(MS)
A	a-1	$\sigma^2 + c\sigma_{\tau\beta}^2 + bc\sigma_\tau^2$
B	b-1	$\sigma^2 + c\sigma_{\tau\beta}^2 + a\sigma_{\beta\gamma}^2 + ac\sigma_\beta^2$
C	c-1	$\sigma^2 + a\sigma_{\beta\gamma}^2 + ab\sigma_\gamma^2$
AB	(a-1)(b-1)	$\sigma^2 + c\sigma_{\tau\beta}^2$
BC	(b-1)(c-1)	$\sigma^2 + a\sigma_{\beta\gamma}^2$
Error (AC + ABC)	b(a-1)(c-1)	σ^2
Total	abc-1	

There are exact tests for all effects except B. To test B, use the statistic $F = \frac{MS_B + MS_E}{MS_{AB} + MS_{BC}}$

13-25 The three-factor model for a single replicate is

$$y_{ijk} = \mu + \tau_i + \beta_j + \gamma_k + (\tau\beta)_{ij} + (\beta\gamma)_{jk} + (\tau\gamma)_{ik} + (\tau\beta\gamma)_{ijk} + \varepsilon_{ijk}$$

If all the factors are random, can any effects be tested? If the three-factor interaction and the $(\tau\beta)_{ij}$ interaction do not exist, can all the remaining effects be tested.

The expected mean squares are found by referring to Table 12-9, deleting the line for the error term $\varepsilon_{(ijk)l}$ and setting $n=1$. The three-factor interaction now cannot be tested; however, exact tests exist for the two-factor interactions and approximate F tests can be conducted for the main effects. For example, to test the main effect of A, use

$$F = \frac{MS_A + MS_{ABC}}{MS_{AB} + MS_{AC}}$$

If $(\tau\beta\gamma)_{ijk}$ and $(\tau\beta)_{ij}$ can be eliminated, the model becomes

$$y_{ijk} = \mu + \tau_i + \beta_j + \gamma_k + (\tau\beta)_{ij} + (\beta\gamma)_{jk} + (\tau\gamma)_{ik} + (\tau\beta\gamma)_{ijk} + \varepsilon_{ijk}$$

For this model, the analysis of variance is

Source	DF	E(MS)
A	a-1	$\sigma^2 + b\sigma_{\tau\gamma}^2 + bc\sigma_\tau^2$
B	b-1	$\sigma^2 + a\sigma_{\beta\gamma}^2 + ac\sigma_\beta^2$
C	c-1	$\sigma^2 + a\sigma_{\beta\gamma}^2 + b\sigma_{\tau\gamma}^2 + ab\sigma_\gamma^2$
AC	(a-1)(c-1)	$\sigma^2 + b\sigma_{\tau\gamma}^2$
BC	(b-1)(c-1)	$\sigma^2 + a\sigma_{\beta\gamma}^2$
Error (AB + ABC)	c(a-1)(b-1)	σ^2
Total	abc-1	

There are exact tests for all effect except C. To test the main effect of C, use the statistic:

$$F = \frac{MS_C + MS_E}{MS_{BC} + MS_{AC}}$$

13-26 In Problem 5-6, assume that both machines and operators were chosen randomly. Determine the power of the test for detecting a machine effect such that $\sigma_\beta^2 = \sigma^2$, where σ_β^2 is the variance component for the machine factor. Are two replicates sufficient?

$$\lambda = \sqrt{1 + \frac{an\sigma_\beta^2}{\sigma^2 + n\sigma_{\tau\beta}^2}}$$

If $\sigma_\beta^2 = \sigma^2$, then an estimate of $\sigma^2 = \sigma_\beta^2 = 3.79$, and an estimate of $\sigma^2 = n\sigma_{\tau\beta}^2 = 7.45$, from the analysis of variance table. Then

$$\lambda = \sqrt{1 + \frac{(3)(2)(3.79)}{7.45}} = \sqrt{2.22} = 1.49$$

and the other OC curve parameters are $\nu_1 = 3$ and $\nu_2 = 6$. This results in $\beta \approx 0.75$ approximately, with $\alpha = 0.05$, or $\beta \approx 0.9$ with $\alpha = 0.01$. Two replicates does not seem sufficient.

13-27 In the two-factor mixed model analysis of variance, show that $\text{Cov}[(\tau\beta)_{ij}, (\tau\beta)_{i'j}] = -(1/a)^2_{\tau\beta\sigma}$ for $i \neq i'$.

Since $\sum_{i=1}^a (\tau\beta)_{ij} = 0$ (constant) we have $V\left[\sum_{i=1}^a (\tau\beta)_{ij}\right] = 0$, which implies that

$$\begin{aligned} \sum_{i=1}^a V(\tau\beta)_{ij} + 2\binom{a}{2} \text{Cov}[(\tau\beta)_{ij}, (\tau\beta)_{i'j}] &= 0 \\ a\left[\frac{a-1}{a}\right]\sigma_{\tau\beta}^2 + \frac{a!}{2!(a-2)!}(2)\text{Cov}[(\tau\beta)_{ij}, (\tau\beta)_{i'j}] &= 0 \\ (a-1)\sigma_{\tau\beta}^2 + a(a-1)\text{Cov}[(\tau\beta)_{ij}, \tau(\beta)_{i'j}] &= 0 \\ \text{Cov}[\tau(\beta)_{ij}, (\tau\beta)_{i'j}] &= -\left(\frac{1}{a}\right)\sigma_{\tau\beta}^2 \end{aligned}$$

13-28 Show that the method of analysis of variance always produces unbiased point estimates of the variance component in any random or mixed model.

Let \mathbf{g} be the vector of mean squares from the analysis of variance, chosen so that $E(\mathbf{g})$ does not contain any fixed effects. Let $\boldsymbol{\sigma}^2$ be the vector of variance components such that $E(\mathbf{g}) = \mathbf{A}\boldsymbol{\sigma}^2$, where \mathbf{A} is a matrix of constants. Now in the analysis of variance method of variance component estimation, we equate observed and expected mean squares, i.e.

$$\mathbf{g} = \mathbf{A}\boldsymbol{\sigma}^2 \Rightarrow \hat{\mathbf{s}}^2 = \mathbf{A}^{-1}\mathbf{g}$$

Since \mathbf{A}^{-1} always exists then,

$$E(\hat{\mathbf{s}}^2) = E(\mathbf{A}^{-1}\mathbf{g}) = \mathbf{A}^{-1}E(\mathbf{g}) = \mathbf{A}^{-1}(\mathbf{A}\boldsymbol{\sigma}^2) = \boldsymbol{\sigma}^2$$

Thus $\hat{\boldsymbol{\sigma}}^2$ is an unbiased estimator of $\boldsymbol{\sigma}^2$. This and other properties of the analysis of variance method are discussed by Searle (1971a).

13-29 Invoking the usual normality assumptions, find an expression for the probability that a negative estimate of a variance component will be obtained by the analysis of variance method. Using this result, write a statement giving the probability that $\hat{\sigma}_\tau^2 < 0$ in a one-factor analysis of variance. Comment on the usefulness of this probability statement.

Suppose $\hat{\sigma}^2 = \frac{MS_1 - MS_2}{c}$, where MS_i for $i=1,2$ are two mean squares and c is a constant. The probability that $\hat{\sigma}_\tau^2 < 0$ (negative) is

$$P\{\hat{\sigma}^2 < 0\} = P\{MS_1 - MS_2 < 0\} = P\left\{\frac{MS_1}{MS_2} < 1\right\} = P\left\{\frac{\frac{MS_1}{E(MS_1)}}{\frac{MS_2}{E(MS_2)}} < \frac{E(MS_1)}{E(MS_2)}\right\} = P\left\{F_{u,v} < \frac{E(MS_1)}{E(MS_2)}\right\}$$

where u is the number of degrees of freedom for MS_1 and v is the number of degrees of freedom for MS_2 . For the one-way model, this equation reduces to

$$P\{\hat{\sigma}^2 < 0\} = P\left\{F_{a-1, N-a} < \frac{\sigma^2}{\sigma^2 + n\sigma_\tau^2}\right\} = P\left\{F_{a-1, N-a} < \frac{1}{1+nk}\right\}$$

where $k = \frac{\sigma_\tau^2}{\sigma^2}$. Using arbitrary values for some of the parameters in this equation will give an experimenter some idea of the probability of obtaining a negative estimate of $\hat{\sigma}_\tau^2 < 0$.

13-30 Analyze the data in Problem 13-9, assuming that the operators are fixed, using both the unrestricted and restricted forms of the mixed models. Compare the results obtained from the two models.

The restricted model is as follows:

Minitab Output

ANOVA: Measurement versus Part, Operator

In the unrestricted model, the F -test for B is different. The F -test for B in the unrestricted model should generally be more conservative, since MS_{AB} will generally be larger than MS_E . However, this is not the case with this particular experiment.

13-31 Consider the two-factor mixed model. Show that the standard error of the fixed factor mean (e.g. A) is $[MS_{AB} / bn]^{1/2}$.

The standard error is often used in Duncan's Multiple Range test. Duncan's Multiple Range Test requires the variance of the difference in two means, say

$$V(\bar{y}_{i..} - \bar{y}_{m..})$$

where rows are fixed and columns are random. Now, assuming all model parameters to be independent, we have the following:

$$(\bar{y}_{i..} - \bar{y}_{m..}) = \tau_i - \tau_m + \frac{1}{b} \sum_{j=1}^b (\tau\beta)_{ij} - \frac{1}{b} \sum_{j=1}^b (\tau\beta)_{mj} + \frac{1}{bn} \sum_{j=1}^b \sum_{k=1}^n \varepsilon_{ijk} - \frac{1}{bn} \sum_{j=1}^b \sum_{k=1}^n \varepsilon_{mjk}$$

and

$$V(\bar{y}_{i..} - \bar{y}_{m..}) = \left(\frac{1}{b}\right)^2 b\sigma_{\tau\beta}^2 + \left(\frac{1}{b}\right)^2 b\sigma_{\tau\beta}^2 + \left(\frac{1}{bn}\right)^2 bn\sigma^2 + \left(\frac{1}{bn}\right)^2 bn\sigma^2 = \frac{2(\sigma^2 + n\sigma_{\tau\beta}^2)}{bn}$$

Since MS_{AB} estimates $\sigma^2 + n\sigma_{\tau\beta}^2$, we would use

$$\frac{2MS_{AB}}{bn}$$

as the standard error to test the difference. However, the table of ranges for Duncan's Multiple Range test already include the constant 2.

13-32 Consider the variance components in the random model from Problem 13-9.

- (a) Find an exact 95 percent confidence interval on σ^2 .

$$\begin{aligned} \frac{f_E MS_E}{\chi_{\alpha/2, f_E}^2} &\leq \sigma^2 \leq \frac{f_E MS_E}{\chi_{1-\alpha/2, f_E}^2} \\ \frac{(40)(1.5)}{59.34} &\leq \sigma^2 \leq \frac{(40)(1.5)}{24.43} \\ 1.011 &\leq \sigma^2 \leq 2.456 \end{aligned}$$

- (b) Find approximate 95 percent confidence intervals on the other variance components using the Satterthwaite method.

$\hat{\sigma}_{\tau\beta}^2$ and $\hat{\sigma}_\tau^2$ are negative, and the Satterthwaite method does not apply. The confidence interval on $\hat{\sigma}_\beta^2$ is

$$\begin{aligned} \hat{\sigma}_\beta^2 &= \frac{MS_B - MS_{AB}}{an} \quad \hat{\sigma}_\beta^2 = \frac{11.001852 - 0.6018519}{2(3)} = 1.7333 \\ r &= \frac{(MS_B - MS_{AB})^2}{\frac{MS_B^2}{(b-1)} + \frac{MS_{AB}^2}{(a-1)(b-1)}} = \frac{(11.001852 - 0.6018519)^2}{\frac{1.001852^2}{(9)} + \frac{0.6018519^2}{(1)(9)}} = 8.01826 \\ \frac{r\hat{\sigma}_\beta^2}{\chi_{\alpha/2, r}^2} &\leq \sigma_\beta^2 \leq \frac{r\hat{\sigma}_\beta^2}{\chi_{1-\alpha/2, r}^2} \\ \frac{(8.01826)(1.7333)}{17.55752} &\leq \sigma_\beta^2 \leq \frac{(8.01826)(1.7333)}{2.18950} \\ 0.79157 &\leq \sigma_\beta^2 \leq 6.34759 \end{aligned}$$

- 13-33** Use the experiment described in Problem 5-6 and assume that both factor are random. Find an exact 95 percent confidence interval on σ^2 . Construct approximate 95 percent confidence interval on the other variance components using the Satterthwaite method.

$$\begin{aligned} \hat{\sigma}^2 &= MS_E \quad \hat{\sigma}^2 = 3.79167 \\ \frac{f_E MS_E}{\chi_{\alpha/2, f_E}^2} &\leq \sigma^2 \leq \frac{f_E MS_E}{\chi_{1-\alpha/2, f_E}^2} \\ \frac{(12)(3.79167)}{23.34} &\leq \sigma^2 \leq \frac{(12)(3.79167)}{4.40} \\ 1.9494 &\leq \sigma^2 \leq 10.3409 \end{aligned}$$

Satterthwaite Method:

$$\begin{aligned} \hat{\sigma}_{\tau\beta}^2 &= \frac{MS_{AB} - MS_E}{n} \quad \hat{\sigma}_{\tau\beta}^2 = \frac{7.44444 - 3.79167}{2} = 1.82639 \\ r &= \frac{(MS_{AB} - MS_E)^2}{\frac{MS_{AB}^2}{(a-1)(b-1)} + \frac{MS_E^2}{df_E}} = \frac{(7.44444 - 3.79167)^2}{\frac{7.44444^2}{(2)(3)} + \frac{3.79167^2}{(12)}} = 2.2940 \\ \frac{r\hat{\sigma}_{\tau\beta}^2}{\chi_{\alpha/2, r}^2} &\leq \sigma_{\tau\beta}^2 \leq \frac{r\hat{\sigma}_{\tau\beta}^2}{\chi_{1-\alpha/2, r}^2} \end{aligned}$$

$$\frac{(2.2940)(1.82639)}{7.95918} \leq \sigma_{\beta}^2 \leq \frac{(2.2940)(1.82639)}{0.09998}$$

$$0.52640 \leq \sigma_{\beta}^2 \leq 41.90577$$

$\hat{\sigma}_{\beta}^2 < 0$, this variance component does not have a confidence interval using Satterthwaite's Method.

$$\hat{\sigma}_{\tau}^2 = \frac{MS_A - MS_{AB}}{bn} \quad \hat{\sigma}_{\tau}^2 = \frac{80.16667 - 7.44444}{4(2)} = 9.09028$$

$$r = \frac{(MS_A - MS_{AB})^2}{\frac{MS_A^2}{(a-1)} + \frac{MS_{AB}^2}{(a-1)(b-1)}} = \frac{(80.16667 - 7.44444)^2}{\frac{80.16667^2}{(2)} + \frac{7.44444^2}{(2)(3)}} = 1.64108$$

$$\frac{r\hat{\sigma}_{\tau}^2}{\chi_{\alpha/2,r}^2} \leq \sigma_{\tau}^2 \leq \frac{r\hat{\sigma}_{\tau}^2}{\chi_{1-\alpha/2,r}^2}$$

$$\frac{(1.64108)(9.09028)}{6.53295} \leq \sigma_{\tau}^2 \leq \frac{(1.64108)(9.09028)}{0.03205}$$

$$2.28348 \leq \sigma_{\tau}^2 \leq 465.45637$$

13-34 Consider the three-factor experiment in Problem 5-17 and assume that operators were selected at random. Find an approximate 95 percent confidence interval on the operator variance component.

$$\hat{\sigma}_{\gamma}^2 = \frac{MS_C - MS_E}{abn} \quad \hat{\sigma}_{\gamma}^2 = \frac{130.66667 - 3.27778}{2(3)(3)} = 7.07716$$

$$r = \frac{(MS_C - MS_E)^2}{\frac{MS_C^2}{(c-1)} + \frac{MS_E^2}{df_E}} = \frac{(130.66667 - 3.27778)^2}{\frac{130.66667^2}{(2)} + \frac{3.27778^2}{(36)}} = 1.90085$$

$$\frac{r\hat{\sigma}_{\gamma}^2}{\chi_{\alpha/2,r}^2} \leq \sigma_{\gamma}^2 \leq \frac{r\hat{\sigma}_{\gamma}^2}{\chi_{1-\alpha/2,r}^2}$$

$$\frac{(1.90085)(7.07716)}{9.15467} \leq \sigma_{\gamma}^2 \leq \frac{(1.90085)(7.07716)}{0.04504}$$

$$1.46948 \leq \sigma_{\gamma}^2 \leq 4298.66532$$

13-35 Rework Problem 13-32 using the modified large-sample approach described in Section 13-7.2. Compare the two sets of confidence intervals obtained and discuss.

$$\hat{\sigma}_O^2 = \hat{\sigma}_{\beta}^2 = \frac{MS_B - MS_{AB}}{an} \quad \hat{\sigma}_O^2 = \frac{11.001852 - 0.6018519}{2(3)} = 1.7333$$

$$G_1 = 1 - \frac{1}{F_{0.05, 9, \infty}} = 1 - \frac{1}{1.88} = 0.46809$$

$$H_1 = \frac{1}{F_{95, 9_i, \infty}} - 1 = \frac{1}{\chi^2_{95, 9}} - 1 = \frac{1}{0.370} - 1 = 1.7027$$

$$G_{ij} = \frac{(F_{\alpha, f_i, f_j} - 1)^2 - G_1^2 F_{\alpha, f_i, f_j} - H_1^2}{F_{\alpha, f_i, f_j}} = \frac{(3.18 - 1)^2 - (0.46809)^2 (3.18) - 1.7027^2}{3.18} = 0.36366$$

$$V_L = G_1^2 c_1^2 MS_B^2 + H_1^2 c_2^2 MS_{AB}^2 + G_{11} c_1 c_2 MS_B MS_{AB}$$

$$V_L = (0.46809)^2 \left(\frac{1}{6}\right)^2 (11.00185)^2 + (1.7027)^2 \left(\frac{1}{6}\right)^2 (0.60185)^2 + (0.36366) \left(\frac{1}{6}\right) \left(\frac{1}{6}\right) (11.00185)(0.60185)$$

$$V_L = 0.83275$$

$$L = \hat{\sigma}_\gamma^2 - \sqrt{V_L} = 1.7333 - \sqrt{0.83275} = 0.82075$$

13-36 Rework Problem 13-34 using the modified large-sample method described in Section 13-7.2. Compare this confidence interval with the one obtained previously and discuss.

$$\hat{\sigma}_\gamma^2 = \frac{MS_C - MS_E}{abn} \quad \hat{\sigma}_\gamma^2 = \frac{130.66667 - 3.277778}{2(3)(3)} = 7.07716$$

$$G_1 = 1 - \frac{1}{F_{0.05, 3, \infty}} = 1 - \frac{1}{2.60} = 0.61538$$

$$H_1 = \frac{1}{F_{95, 36, \infty}} - 1 = \frac{1}{\chi^2_{95, 36}} - 1 = \frac{1}{0.64728} - 1 = 0.54493$$

$$G_{ij} = \frac{(F_{\alpha, f_i, f_j} - 1)^2 - G_1^2 F_{\alpha, f_i, f_j} - H_1^2}{F_{\alpha, f_i, f_j}} = \frac{(2.88 - 1)^2 - (0.61538)^2 (2.88) - 0.54493^2}{2.88} = 0.74542$$

$$V_L = G_1^2 c_1^2 MS_B^2 + H_1^2 c_2^2 MS_{AB}^2 + G_{11} c_1 c_2 MS_B MS_{AB}$$

$$V_L = (0.61538)^2 \left(\frac{1}{18}\right)^2 (130.66667)^2 + (0.54493)^2 \left(\frac{1}{18}\right)^2 (3.27778)^2 + (0.74542) \left(\frac{1}{18}\right) \left(\frac{1}{18}\right) (130.66667)(3.27778)$$

$$V_L = 20.95112$$

$$L = \hat{\sigma}_\gamma^2 - \sqrt{V_L} = 7.07716 - \sqrt{20.95112} = 2.49992$$

Chapter 14

Nested and Split-Plot Designs

Solutions

In this chapter we have not shown residual plots and other diagnostics to conserve space. A complete analysis would, of course, include these model adequacy checking procedures.

14-1 A rocket propellant manufacturer is studying the burning rate of propellant from three production processes. Four batches of propellant are randomly selected from the output of each process and three determinations of burning rate are made on each batch. The results follow. Analyze the data and draw conclusions.

Batch	Process 1				Process 2				Process 3			
	1	2	3	4	1	2	3	4	1	2	3	4
	25	19	15	15	19	23	18	35	14	35	38	25
	30	28	17	16	17	24	21	27	15	21	54	29
	26	20	14	13	14	21	17	25	20	24	50	33

Minitab Output

ANOVA: Burn Rate versus Process, Batch

Factor	Type	Levels	Values
Process	fixed	3	1 2 3
Batch(Process)	random	4	1 2 3 4

Analysis of Variance for Burn Rat

Source	DF	SS	MS	F	P
Process	2	676.06	338.03	1.46	0.281
Batch(Process)	9	2077.58	230.84	12.20	0.000
Error	24	454.00	18.92		
Total	35	3207.64			

Source	Variance Component	Error term	Expected Mean Square for Each Term	using restricted model
1 Process	2	(3)	(3)(2)	+ 12Q[1]
2 Batch(Process)	70.64	3	(3)	+ 3(2)
3 Error	18.92		(3)	

There is no significant effect on mean burning rate among the different processes; however, different batches from the same process have significantly different burning rates.

14-2 The surface finish of metal parts made on four machines is being studied. An experiment is conducted in which each machine is run by three different operators and two specimens from each operator are collected and tested. Because of the location of the machines, different operators are used on each machine, and the operators are chosen at random. The data are shown in the following table. Analyze the data and draw conclusions.

Operator	Machine 1			Machine 2			Machine 3			Machine 4		
	1	2	3	1	2	3	1	2	3	1	2	3
	79	94	46	92	85	76	88	53	46	36	40	62
	62	74	57	99	79	68	75	56	57	53	56	47

Minitab Output

ANOVA: Finish versus Machine, Operator

Factor	Type	Levels	Values			
Machine	fixed	4	1	2	3	4
Operator(Machine)	random	3	1	2	3	
Analysis of Variance for Finish						
Source DF SS MS F P Machine 3 3617.67 1205.89 3.42 0.073 Operator(Machine) 8 2817.67 352.21 4.17 0.013 Error 12 1014.00 84.50 Total 23 7449.33

There is a slight effect on surface finish due to the different processes; however, the different operators running the same machine have significantly different surface finish.

- 14-3** A manufacturing engineer is studying the dimensional variability of a particular component that is produced on three machines. Each machine has two spindles, and four components are randomly selected from each spindle. These results follow. Analyze the data, assuming that machines and spindles are fixed factors.

Spindle	Machine 1		Machine 2		Machine 3	
	1	2	1	2	1	2
	12	8	14	12	14	16
	9	9	15	10	10	15
	11	10	13	11	12	15
	12	8	14	13	11	14

Minitab Output

ANOVA: Variability versus Machine, Spindle

Factor	Type	Levels	Values			
Machine	fixed	3	1	2	3	
Spindle(Machine)	fixed	2	1	2		
Analysis of Variance for Variabil						
Source DF SS MS F P Machine 2 55.750 27.875 18.93 0.000 Spindle(Machine) 3 43.750 14.583 9.91 0.000 Error 18 26.500 1.472 Total 23 126.000						

There is a significant effect on dimensional variability due to the machine and spindle factors.

- 14-4** To simplify production scheduling, an industrial engineer is studying the possibility of assigning one time standard to a particular class of jobs, believing that differences between jobs is negligible. To see if this simplification is possible, six jobs are randomly selected. Each job is given to a different group of three operators. Each operator completes the job twice at different times during the week, and the following results were obtained. What are your conclusions about the use of a common time standard for all jobs in this class? What value would you use for the standard?

Job	Operator 1		Operator 2		Operator 3	
	1	2	1	2	1	2
1	158.3	159.4	159.2	159.6	158.9	157.8
2	154.6	154.9	157.7	156.8	154.8	156.3

3	162.5	162.6	161.0	158.9	160.5	159.5
4	160.0	158.7	157.5	158.9	161.1	158.5
5	156.3	158.1	158.3	156.9	157.7	156.9
6	163.7	161.0	162.3	160.3	162.6	161.8

Minitab Output

ANOVA: Time versus Job, Operator

Factor	Type	Levels	Values				
Job	random	6	1	2	3	4	5
Operator(Job)	random	3	1	2	3		
Analysis of Variance for Time							
Source	DF	SS	MS	F	P		
Job	5	148.111	29.622	27.89	0.000		
Operator(Job)	12	12.743	1.062	0.69	0.738		
Error	18	27.575	1.532				
Total	35	188.430					
Source	Variance	Error	Expected Mean Square for Each Term				
component term (using restricted model)							
1 Job	4.7601	2	(3) + 2(2) + 6(1)				
2 Operator(Job)	-0.2350	3	(3) + 2(2)				
3 Error	1.5319		(3)				

The jobs differ significantly; the use of a common time standard would likely not be a good idea.

14-5 Consider the three-stage nested design shown in Figure 13-5 to investigate alloy hardness. Using the data that follow, analyze the design, assuming that alloy chemistry and heats are fixed factors and ingots are random.

Alloy Chemistry												
Heats	1			2			1			2		
	1	2	1	2	1	2	1	2	1	2	1	2
Ingots	40	27	95	69	65	78	22	23	83	75	61	35
	63	30	67	47	54	45	10	39	62	64	77	42

Minitab Output

ANOVA: Hardness versus Alloy, Heat, Ingot

Factor	Type	Levels	Values				
Alloy	fixed	2	1	2			
Heat(Alloy)	fixed	3	1	2	3		
Ingot(Alloy Heat)	random	2	1	2			

Analysis of Variance for Hardness

Source	DF	SS	MS	F	P
Alloy	1	315.4	315.4	0.85	0.392
Heat(Alloy)	4	6453.8	1613.5	4.35	0.055
Ingot(Alloy Heat)	6	2226.3	371.0	2.08	0.132
Error	12	2141.5	178.5		
Total	23	11137.0			

Source	Variance	Error	Expected Mean Square for Each Term		
component term (using restricted model)					
1 Alloy	3	(4) + 2(3) + 12Q[1]			
2 Heat(Alloy)	3	(4) + 2(3) + 4Q[2]			
3 Ingot(Alloy Heat)	96.29	4	(4) + 2(3)		
4 Error	178.46		(4)		

Alloy hardness differs significantly due to the different heats within each alloy.

- 14-6** Reanalyze the experiment in Problem 14-5 using the unrestricted form of the mixed model. Comment on any differences you observe between the restricted and unrestricted model results. You may use a computer software package.

Minitab Output

ANOVA: Hardness versus Alloy, Heat, Ingot

Factor	Type	Levels	Values
Alloy	fixed	2	1 2
Heat(Alloy)	fixed	3	1 2 3
Ingot(Alloy Heat)	random	2	1 2

Analysis of Variance for Hardness

Source	DF	SS	MS	F	P
Alloy	1	315.4	315.4	0.85	0.392
Heat(Alloy)	4	6453.8	1613.5	4.35	0.055
Ingot(Alloy Heat)	6	2226.3	371.0	2.08	0.132
Error	12	2141.5	178.5		
Total	23	11137.0			

Source	Variance Component	Error term	Expected Mean Square for Each Term (using unrestricted model)
1 Alloy	3	(4) + 2(3) + Q[1,2]

3 Ingot(Alloy Heat)	96.29	4 (4) + 2(3)	
4 Error	178.46	(4)	

- 14-7** Derive the expected means squares for a balanced three-stage nested design, assuming that A is fixed and that B and C are random. Obtain formulas for estimating the variance components.

The expected mean squares can be generated in Minitab as follows:

Minitab Output

ANOVA: y versus A, B, C

Factor	Type	Levels	Values
A	fixed	2	-1 1
B(A)	random	2	-1 1
C(A B)	random	2	-1 1

Analysis of Variance for y

Source	DF	SS	MS	F	P
A	1	0.250	0.250	0.06	0.831
B(A)	2	8.500	4.250	0.35	0.726
C(A B)	4	49.000	12.250	2.13	0.168
Error	8	46.000	5.750		
Total	15	103.750			

Source	Variance Component	Error term	Expected Mean Square for Each Term (using restricted model)
1 A	2	(4) + 2(3) + 4(2) + 8Q[1]	
2 B(A)	-2.000	3 (4) + 2(3) + 4(2)	
3 C(A B)	3.250	4 (4) + 2(3)	
4 Error	5.750	(4)	

- 14-8** Repeat Problem 14-7 assuming the unrestricted form of the mixed model. You may use a computer software package. Comment on any differences you observe between the restricted and unrestricted model analysis and conclusions.

Minitab Output

ANOVA: y versus A, B, C					
Factor Type Levels Values					
A	fixed	2	-1	1	
B(A)	random	2	-1	1	
C(A B)	random	2	-1	1	
Analysis of Variance for y					
Source	DF	SS	MS	F	P
A	1	0.250	0.250	0.06	0.831
B(A)	2	8.500	4.250	0.35	0.726
C(A B)	4	49.000	12.250	2.13	0.168
Error	8	46.000	5.750		
Total	15	103.750			
Source	Variance Error Expected Mean Square for Each Term component term (using unrestricted model)				
1 A	2	(4) + 2(3) + 4(2) + Q[1]			
2 B(A)	3	(4) + 2(3) + 4(2)			
3 C(A B)	4	(4) + 2(3)			
4 Error	5.750	(4)			

In this case there is no difference in results between the restricted and unrestricted models.

14-9 Derive the expected means squares for a balanced three-stage nested design if all three factors are random. Obtain formulas for estimating the variance components. Assume the restricted form of the mixed model.

The expected mean squares can be generated in Minitab as follows:

Minitab Output

ANOVA: y versus A, B, C

A	random	2	-1	1	
B(A)	random	2	-1	1	
C(A B)	random	2	-1	1	
Analysis of Variance for y					
Source	DF	SS	MS	F	P
A	1	0.250	0.250	0.06	0.831
B(A)	2	8.500	4.250	0.35	0.726
C(A B)	4	49.000	12.250	2.13	0.168
Error	8	46.000	5.750		
Total	15	103.750			
Source	Variance Error Expected Mean Square for Each Term component term (using unrestricted model)				
1 A	-0.5000	2	(4) + 2(3) + 4(2) + 8(1)		
2 B(A)	-2.0000	3	(4) + 2(3) + 4(2)		
3 C(A B)	3.2500	4	(4) + 2(3)		
4 Error	5.7500	(4)			

14-10 Verify the expected mean squares given in Table 14-1.

Factor	F	F	R	E(MS)
	a	b	n	
	i	j	l	
τ_i	0	b	n	$\sigma^2 + \frac{bn}{a-1} \sum \tau_i^2$

$\beta_{j(i)}$	1	0	n	$\sigma^2 + \frac{n}{a(b-1)} \sum \sum \beta_{j(i)}^2$
$\varepsilon_{(ijk)l}$	1	1	1	σ^2

Factor	R	R	R	
	a	b	n	E(MS)
τ_i	1	b	n	$\sigma^2 + n\sigma_\beta^2 + bn\sigma_\tau^2$
$\beta_{j(i)}$	1	1	n	$\sigma^2 + n\sigma_\beta^2$
$\varepsilon_{(ijk)l}$	1	1	1	σ^2

Factor	F	R	R	
	a	b	n	E(MS)
τ_i	0	b	n	$\sigma^2 + n\sigma_\beta^2 + \frac{bn}{a-1} \sum \tau_i^2$
$\beta_{j(i)}$	1	1	n	$\sigma^2 + n\sigma_\beta^2$
$\varepsilon_{(ijk)l}$	1	1	1	σ^2

14-11 Unbalanced designs. Consider an unbalanced two-stage nested design with b_j levels of B under the i th level of A and n_{ij} replicates in the ijk th cell.

(a) Write down the least squares normal equations for this situation. Solve the normal equations.

The least squares normal equations are:

$$\begin{aligned}\mu &= n_{..} \hat{\mu} + \sum_{i=1}^a n_{i..} \hat{\tau}_i + \sum_{i=1}^a \sum_{j=1}^{b_i} n_{ij} \hat{\beta}_{j(i)} = y_{...} \\ \tau_i &= n_{i..} \hat{\mu} + n_{i..} \hat{\tau}_i + \sum_{j=1}^{b_i} n_{ij} \hat{\beta}_{j(i)} = y_{i..}, \text{ for } i = 1, 2, \dots, a \\ \beta_{j(i)} &= n_{ij} \hat{\mu} + n_{ij} \hat{\tau}_i + n_{ij} \hat{\beta}_{j(i)} = y_{ij}, \text{ for } i = 1, 2, \dots, a \text{ and } j = 1, 2, \dots, b_i\end{aligned}$$

There are $1+a+b$ equations in $1+a+b$ unknowns. However, there are $a+1$ linear dependencies in these equations, and consequently, $a+1$ side conditions are needed to solve them. Any convenient set of $a+1$ linearly independent equations can be used. The easiest set is $\hat{\mu} = 0$, $\hat{\tau}_i = 0$, for $i=1,2,\dots,a$. Using these conditions we get

$$\hat{\mu} = 0, \hat{\tau}_i = 0, \hat{\beta}_{j(i)} = \bar{y}_{ij}.$$

as the solution to the normal equations. See Searle (1971) for a full discussion.

(b) Construct the analysis of variance table for the unbalanced two-stage nested design.

The analysis of variance table is

Source	SS	DF
--------	----	----

A	$\sum_{i=1}^a \frac{y_{i..}^2}{n_{i..}} - \frac{y_{...}^2}{n_{..}}$	$a-1$
B	$\sum_{i=1}^a \sum_{j=1}^{b_i} \frac{y_{ij..}^2}{n_{ij..}} - \sum_{i=1}^a \frac{y_{i..}^2}{n_{i..}}$	$b-a$
Error	$\sum_{i=1}^a \sum_{j=1}^{b_i} \sum_{k=1}^{n_{ij..}} y_{ijk..}^2 - \sum_{i=1}^a \sum_{j=1}^{b_i} \frac{y_{ij..}^2}{n_{ij..}}$	$n..-b$
Total	$\sum_{i=1}^a \sum_{j=1}^{b_i} \sum_{k=1}^{n_{ij..}} y_{ijk..}^2 - \frac{y_{...}^2}{n_{..}}$	$n..-1$

(c) Analyze the following data, using the results in part (b).

Factor A		1		2	
Factor B		1	2	1	2
		6	-3	5	2
		4	1	7	4
		8		9	3
					6

Note that $a=2$, $b_1=2$, $b_2=3$, $b=b_1+b_2=5$, $n_{11}=3$, $n_{12}=2$, $n_{21}=4$, $n_{22}=3$ and $n_{23}=3$

Source	SS	DF	MS
A	0.13	1	0.13
B	153.78	3	51.26
Error	35.42	10	3.54
Total	189.33	14	

The analysis can also be performed in Minitab as follows. The adjusted sum of squares is utilized by Minitab's general linear model routine.

Minitab Output

General Linear Model: y versus A, B

```
Factor      Type Levels Values
A          fixed    2 1 2
B(A)       fixed    5 1 2 1 2 3
```

14-12 Variance components in the unbalanced two-stage nested design. Consider the model

$$y_{ijk} = \mu + \tau_i + \beta_{j(i)} + \varepsilon_{k(j)} \quad \begin{cases} i = 1, 2, \dots, a \\ j = 1, 2, \dots, b \\ k = 1, 2, \dots, n_{ij} \end{cases}$$

where A and B are random factors. Show that

$$E(MS_A) = \sigma^2 + c_1\sigma_\beta^2 + c_2\sigma_\tau^2$$

$$E(MS_{B(A)}) = \sigma^2 + c_0\sigma_\beta^2$$

$$E(MS_E) = \sigma^2$$

where

$$c_0 = \frac{N - \sum_{i=1}^a \left(\sum_{j=1}^{b_i} \frac{n_{ij}^2}{n_{i.}} \right)}{b - a}$$

$$c_1 = \frac{\sum_{i=1}^a \left(\sum_{j=1}^{b_i} \frac{n_{ij}^2}{n_{i.}} \right) - \sum_{i=1}^a \sum_{j=1}^{b_i} \frac{n_{ij}^2}{N}}{a - 1}$$

$$c_2 = \frac{N - \frac{\sum_{i=1}^a n_{i.}^2}{N}}{a - 1}$$

See "Variance Component Estimation in the 2-way Nested Classification," by S.R. Searle, *Annals of Mathematical Statistics*, Vol. 32, pp. 1161-1166, 1961. A good discussion of variance component estimation from unbalanced data is in Searle (1971a).

14-13 A process engineer is testing the yield of a product manufactured on three machines. Each machine can be operated at two power settings. Furthermore, a machine has three stations on which the product is formed. An experiment is conducted in which each machine is tested at both power settings, and three observations on yield are taken from each station. The runs are made in random order, and the results follow. Analyze this experiment, assuming all three factors are fixed.

Station	Machine 1			Machine 2			Machine 3		
	1	2	3	1	2	3	1	2	3
Power Setting 1	34.1	33.7	36.2	32.1	33.1	32.8	32.9	33.8	33.6
	30.3	34.9	36.8	33.5	34.7	35.1	33.0	33.4	32.8
	31.6	35.0	37.1	34.0	33.9	34.3	33.1	32.8	31.7
Power Setting 2	24.3	28.1	25.7	24.1	24.1	26.0	24.2	23.2	24.7
	26.3	29.3	26.1	25.0	25.1	27.1	26.1	27.4	22.0
	27.1	28.6	24.9	26.3	27.9	23.9	25.3	28.0	24.8

The linear model is $y_{ijkl} = \mu + \tau_i + \beta_j + (\tau\beta)_{ij} + \gamma_{k(j)} + (\tau\gamma)_{ik(j)} + \varepsilon_{(ijk)l}$

Minitab Output

There are differences between several of the expected mean squares. However, the conclusions that could be drawn do not differ in any meaningful way from the restricted model analysis.

14-16 A structural engineer is studying the strength of aluminum alloy purchased from three vendors. Each vendor submits the alloy in standard-sized bars of 1.0, 1.5, or 2.0 inches. The processing of different sizes of bar stock from a common ingot involves different forging techniques, and so this factor may be important. Furthermore, the bar stock is forged from ingots made in different heats. Each vendor submits two tests specimens of each size bar stock from the three heats. The resulting strength data follow. Analyze the data, assuming that vendors and bar size are fixed and heats are random.

Heat	Vendor 1			Vendor 2			Vendor 3

14-19 Steel is normalized by heating above the critical temperature, soaking, and then air cooling. This process increases the strength of the steel, refines the grain, and homogenizes the structure. An experiment is performed to determine the effect of temperature and heat treatment time on the strength of normalized steel. Two temperatures and three times are selected. The experiment is performed by heating the oven to a randomly selected temperature and inserting three specimens. After 10 minutes one specimen is removed, after 20 minutes the second specimen is removed, and after 30 minutes the final specimen is removed. Then the temperature is changed to the other level and the process is repeated. Four shifts are required to collect the data, which are shown below. Analyze the data and draw conclusions, assume both factors are fixed.

Shift	Time(minutes)	Temperature (F)	
		1500	1600
1	10	63	89
	20	54	91
	30	61	62
2	10	50	80
	20	52	72
	30	59	69
3	10	48	73
	20	74	81
	30	71	69
4	10	54	88
	20	48	92
	30	59	64

This is a split-plot design. Shifts correspond to blocks, temperature is the whole plot treatment, and time is the subtreatments (in the subplot or split-plot part of the design). The expected mean squares and analysis of variance are shown below. The following Minitab Output has been modified to display the results of the split-plot analysis. Minitab will calculate the sums of squares correctly, but the expected mean squares and the statistical tests are not, in general, correct. Notice that the Error term in the analysis of variance is actually the three factor interaction.

14-20 An experiment is designed to study pigment dispersion in paint. Four different mixes of a particular pigment are studied. The procedure consists of preparing a particular mix and then applying that mix to a panel by three application methods (brushing, spraying, and rolling). The response measured is the percentage reflectance of the pigment. Three days are required to run the experiment, and the data obtained follow. Analyze the data and draw conclusions, assuming that mixes and application methods are fixed.

Day	App Method	Mix			
		1	2	3	4
1	1	64.5	66.3	74.1	66.5
	2	68.3	69.5	73.8	70.0

14-21 Repeat Problem 14-20, assuming that the mixes are random and the application methods are fixed.

The F-tests are the same as those in Problem 13-20. The following Minitab Output has been edited to display the results of the split-plot analysis. Minitab will calculate the sums of squares correctly, but the expected mean squares and the statistical tests are not, in general, correct. Again, the Error term in the analysis of variance is actually the three factor interaction.

Minitab Output

Using the computer output, the F-ratios were calculated by hand using the expected mean squares found in Table 14-18. The following Minitab Output has been edited to display the results of the split-plot analysis. Minitab will calculate the sums of squares correctly, but the expected mean squares and the statistical tests are not, in general, correct. Notice that the Error term in the analysis of variance is actually the four factor interaction.

There are no exact tests on technicians β_j , dosage strengths γ_k , wall thickness δ_h , or the technician x wall thickness interaction $(\beta\delta)_{jh}$. The approximate F-tests are as follows:

$$H_0: \beta_j = 0$$

$$F = \frac{MS_B + MS_{ABC}}{MS_{AB} + MS_{BC}} = \frac{124.174 + 9.491}{26.859 + 31.486} = 2.291$$

$$p = \frac{(MS_B + MS_{ABC})^2}{\frac{MS_B^2}{2} + \frac{MS_{ABC}^2}{12}} = \frac{(124.174 + 9.491)^2}{\frac{124.174^2}{2} + \frac{9.491^2}{12}} = 2.315$$

$$q = \frac{\left(MS_{AB} + MS_{BC}\right)^2}{\frac{MS_{AB}^2}{6} + \frac{MS_{BC}^2}{4}} = \frac{(26.859 + 31.486)^2}{\frac{26.859^2}{6} + \frac{31.486^2}{4}} = 9.248$$

Do not reject $H_0: \beta_j = 0$

$H_0: \gamma_k = 0$

$$F = \frac{MS_C + MS_{ACD}}{MS_{CD} + MS_{AD}} = \frac{10285.028 + 3.914}{67.046 + 34.791} = 101.039$$

$$p = \frac{\left(MS_C + MS_{ACD}\right)^2}{\frac{MS_C^2}{2} + \frac{MS_{ACD}^2}{18}} = \frac{(10285.028 + 3.914)^2}{\frac{10285.028^2}{2} + \frac{3.914^2}{18}} = 2.002$$

$$q = \frac{\left(MS_{CD} + MS_{AD}\right)^2}{\frac{MS_{CD}^2}{6} + \frac{MS_{AD}^2}{9}} = \frac{(67.046 + 34.791)^2}{\frac{67.046^2}{6} + \frac{34.791^2}{9}} = 11.736$$

Reject $H_0: \gamma_k = 0$

$H_0: \delta_h = 0$

$$F = \frac{MS_D + MS_{ACD}}{MS_{CD} + MS_{AD}} = \frac{1268.970 + 3.914}{67.046 + 34.791} = 12.499$$

$$p = \frac{\left(MS_D + MS_{ACD}\right)^2}{\frac{MS_D^2}{3} + \frac{MS_{ACD}^2}{18}} = \frac{(1268.970 + 3.914)^2}{\frac{1268.970^2}{3} + \frac{3.914^2}{18}} = 3.019$$

$$q = \frac{\left(MS_{CD} + MS_{AD}\right)^2}{\frac{MS_{CD}^2}{6} + \frac{MS_{AD}^2}{9}} = \frac{(67.046 + 34.791)^2}{\frac{67.046^2}{6} + \frac{34.791^2}{9}} = 11.736$$

Reject $H_0: \delta_h = 0$

$H_0: (\beta\delta)_{jh} = 0$

$$F = \frac{MS_{BD} + MS_{ABCD}}{MS_{BCD} + MS_{ABD}} = \frac{21.081 + 4.779}{17.157 + 9.309} = 0.977$$

$F < 1$, Do not reject $H_0: (\beta\delta)_{jh} = 0$

14-24 Suppose that in Problem 14-22 four technicians had been used. Assuming that all the factors are fixed, how many blocks should be run to obtain an adequate number of degrees of freedom on the test for differences among technicians?

The number of degrees of freedom for the test is $(a-1)(4-1)=3(a-1)$, where a is the number of blocks used.

Number of Blocks (a)	DF for test
2	3
3	6
4	9
5	12

At least three blocks should be run, but four would give a better test.

14-25 Consider the experiment described in Example 14-4. Demonstrate how the order in which the treatments combinations are run would be determined if this experiment were run as (a) a split-split-plot, (b) a split-plot, (c) a factorial design in a randomized block, and (d) a completely randomized factorial design.

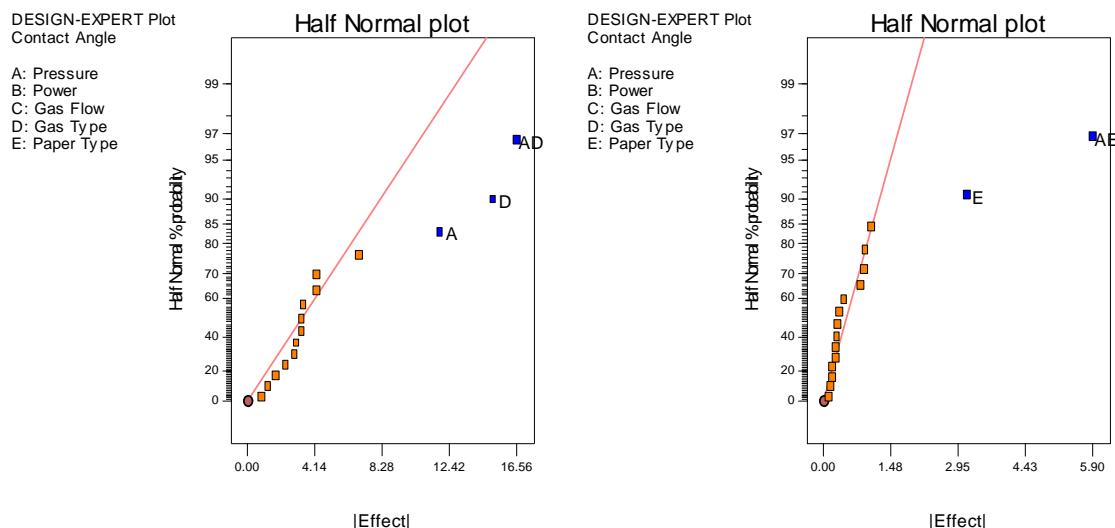

- (a) Randomization for the split-split plot design is described in Example 14-4.
- (b) In the split-plot, within a block, the technicians would be the main treatment and within a block-technician plot, the 12 combinations of dosage strength and wall thickness would be run in random order. The design would be a two-factor factorial in a split-plot.
- (c) To run the design in a randomized block, the 36 combinations of technician, dosage strength, and wall thickness would be run in random order within each block. The design would be a three factor factorial in a randomized block.
- (d) The blocks would be considered as replicates, and all 144 observations would be 4 replicates of a three factor factorial.

14-26 An article in *Quality Engineering* (“Quality Quandaries: Two-Level Factorials Run as Split-Plot Experiments”, Bisgaard, et al, Vol. 8, No. 4, pp. 705-708, 1996) describes a 2^5 factorial experiment on a plasma process focused on making paper more susceptible to ink. Four of the factors ($A-D$) are difficult to change from run-to-run, so the experimenters set up the reactor at the eight sets of conditions specific by the low and high levels of these factors, and then processed the two paper types (factor E) together. The placement of the paper specimens in the reactors (right versus left) was randomized. This produces a split-plot design with $A-D$ as the whole-plot factors and factor E as the subplot factor. The data from this experiment are shown below. Analyze the data from this experiment and draw conclusions.

Standard Order	Run Number	$A =$ Pressure	$B =$ Power	$C =$ Gas Flow	$D =$ Gas Type	$E =$ Paper Type	y Contact Angle
1	23	-1	-1	-1	Oxygen	E1	48.6
2	3	+1	-1	-1	Oxygen	E1	41.2
3	11	-1	+1	-1	Oxygen	E1	55.8

 +17.14375 * Pressure

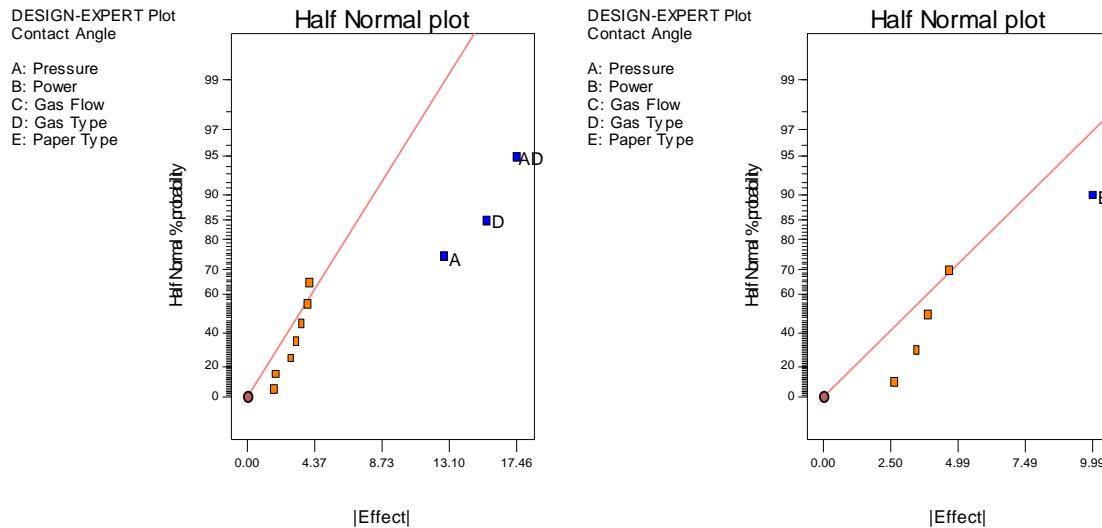

Gas Type Oxygen
 Paper Type E2
 Contact Angle =
 +50.10000
 -5.31875 * Pressure

Gas Type SiCl4
 Paper Type E2
 Contact Angle =
 +35.00000
 +11.24375 * Pressure

- 14-27** Reconsider the experiment in problem 14-26. This is a rather large experiment, so suppose that the experimenter had used a 2^{5-1} design instead. Set up the 2^{5-1} design in a split-plot, using the principle fraction. Then select the response data using the information from the full factorial. Analyze the data and draw conclusions. Do they agree with the results of Problem 14-26?

Standard Order	Run Number	A = Pressure	B = Power	C = Gas Flow	D = Gas Type	E = Paper Type	y Contact Angle
1	12	-1	-1	-1	Oxygen	E2	57
2	2	+1	-1	-1	Oxygen	E1	41.2
3	6	-1	+1	-1	Oxygen	E1	55.8
4	15	+1	+1	-1	Oxygen	E2	51.3
5	1	-1	-1	+1	Oxygen	E1	37.6
6	8	+1	-1	+1	Oxygen	E2	44.8
7	14	-1	+1	+1	Oxygen	E2	54.6
8	13	+1	+1	+1	Oxygen	E1	48.7
9	10	-1	-1	-1	SiCl4	E1	5
10	3	+1	-1	-1	SiCl4	E2	56.2
11	5	-1	+1	-1	SiCl4	E2	33
12	16	+1	+1	-1	SiCl4	E1	41.8
13	7	-1	-1	+1	SiCl4	E2	23.7
14	4	+1	-1	+1	SiCl4	E1	47.5
15	11	-1	+1	+1	SiCl4	E1	11.3
16	9	+1	+1	+1	SiCl4	E2	48.2

Similar results are found with the half fraction other than the AE interaction is no longer significant and the effect for factor E is larger. The half normal probability plot of effects for the whole and sub-plots are shown below. The resulting model is also shown.

Chapter 15

Other Design and Analysis Topics

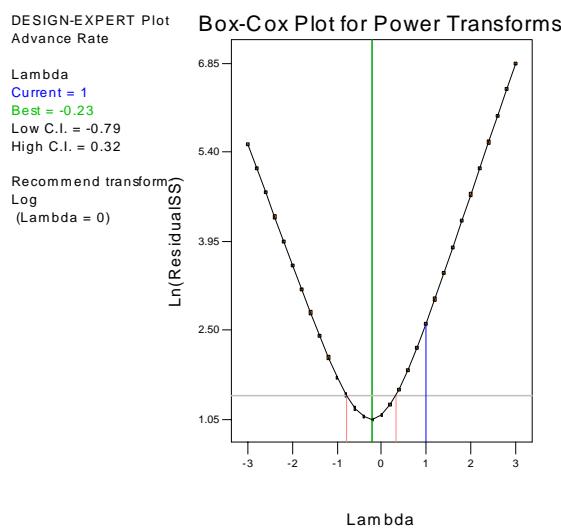

Solutions

15-1 Reconsider the experiment in Problem 5-22. Use the Box-Cox procedure to determine if a transformation on the response is appropriate (or useful) in the analysis of the data from this experiment.

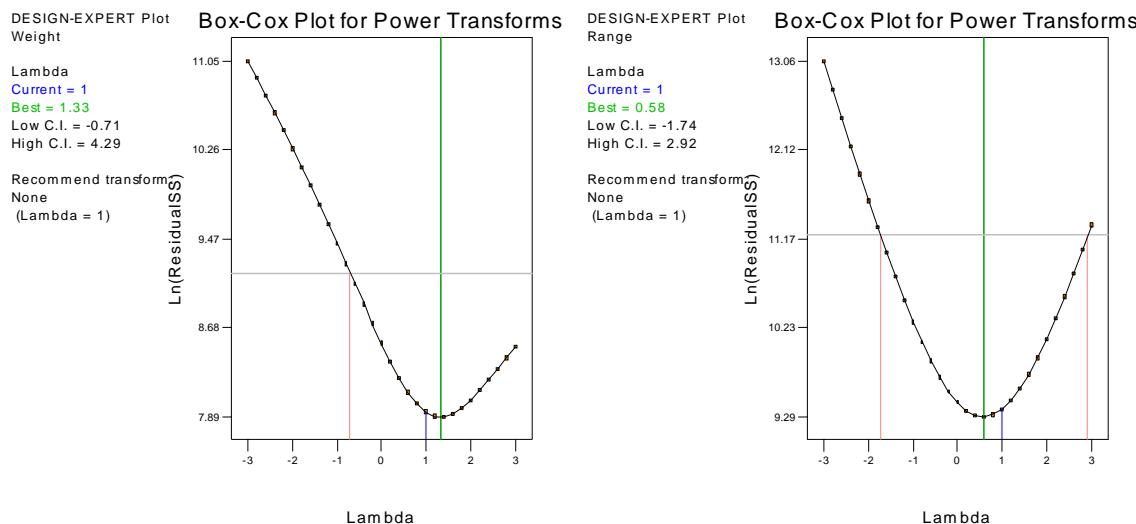

With the value of lambda near zero, and since the confidence interval does not include one, a natural log transformation would be appropriate.

15-2 In example 6-3 we selected a log transformation for the drill advance rate response. Use the Box-Cox procedure to demonstrate that this is an appropriate data transformation.

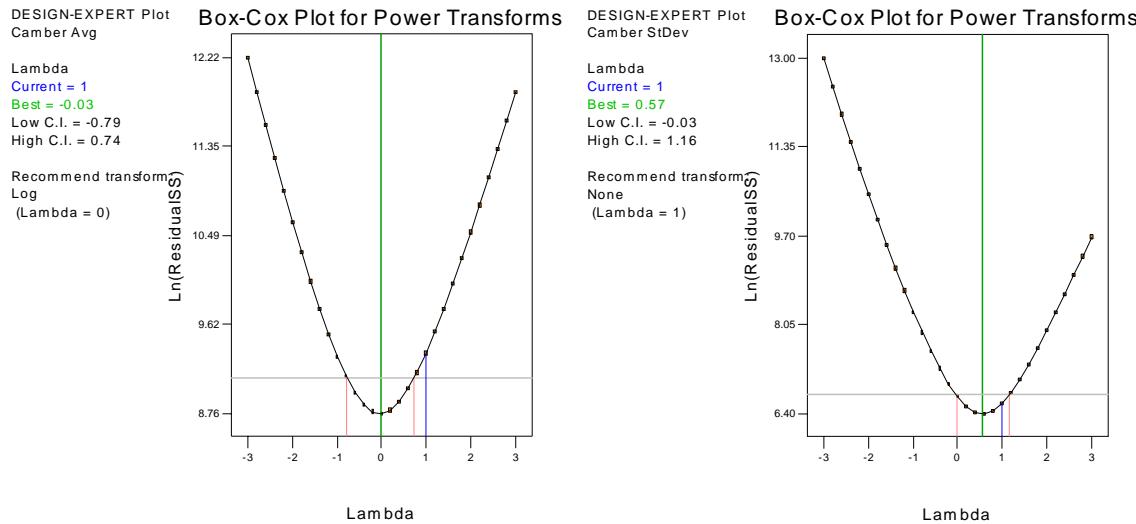

Because the value of lambda is very close to zero, and the confidence interval does not include one, the natural log was the correct transformation chosen for this analysis.

- 15-3** Reconsider the smelting process experiment in Problem 8-23, where a 2^{6-3} fractional factorial design was used to study the weight of packing material stuck to carbon anodes after baking. Each of the eight runs in the design was replicated three times and both the average weight and the range of the weights at each test combination were treated as response variables. Is there any indication that a transformation is required for either response?

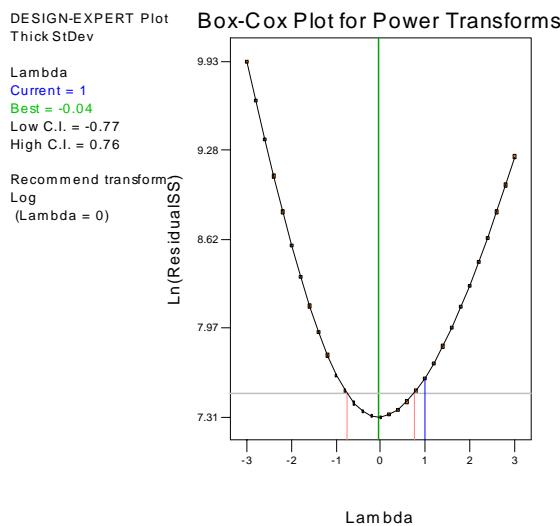

There is no indication that a transformation is required for either response.

- 15-4** In Problem 8-25 a replicated fractional factorial design was used to study substrate camber in semiconductor manufacturing. Both the mean and standard deviation of the camber measurements were used as response variables. Is there any indication that a transformation is required for either response?

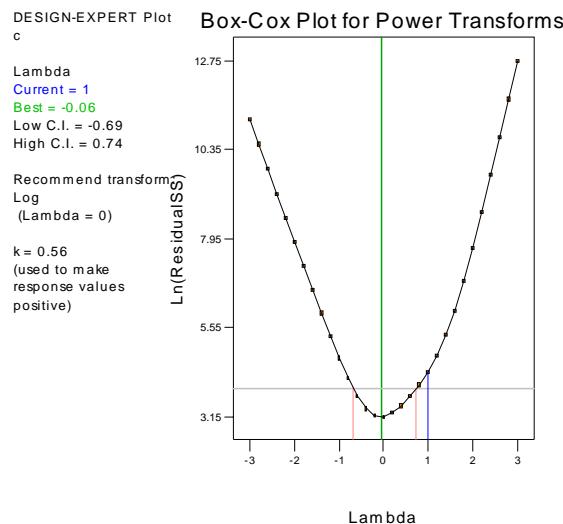

The Box-Cox plot for the Camber Average suggests a natural log transformation should be applied. This decision is based on the confidence interval for lambda not including one and the point estimate of lambda being very close to zero. With a lambda of approximately 0.5, a square root transformation could be considered for the Camber Standard Deviation; however, the confidence interval indicates that no transformation is needed.

15-5 Reconsider the photoresist experiment in Problem 8-26. Use the variance of the resist thickness at each test combination as the response variable. Is there any indication that a transformation is required?

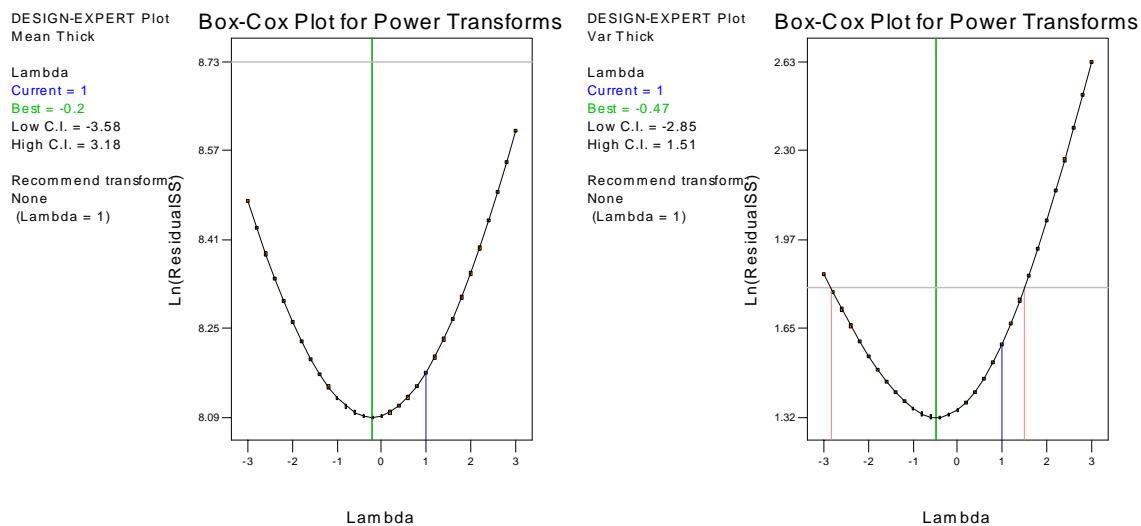

With the point estimate of lambda near zero, and the confidence interval for lambda not inclusive of one, a natural log transformation would be appropriate.

15-6 In the grill defects experiment described in Problem 8-30 a variation of the square root transformation was employed in the analysis of the data. Use the Box-Cox method to determine if this is the appropriate transformation.

Because the confidence interval for the minimum lambda does not include one, the decision to use a transformation is correct. Because the lambda point estimate is close to zero, the natural log transformation would be appropriate. This is a stronger transformation than the square root.

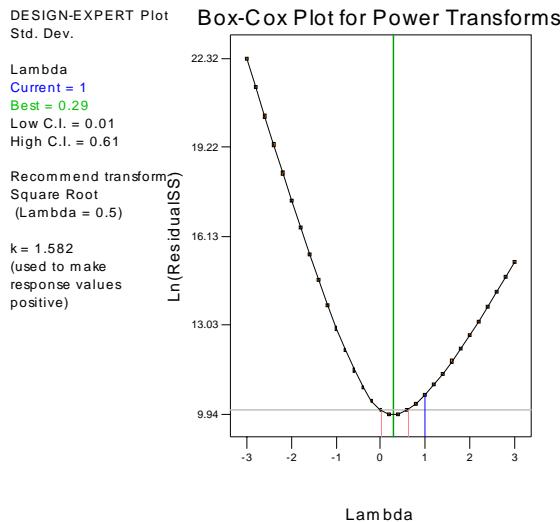

15-7 In the central composite design of Problem 11-14, two responses were obtained, the mean and variance of an oxide thickness. Use the Box-Cox method to investigate the potential usefulness of transformation for both of these responses. Is the log transformation suggested in part (c) of that problem appropriate?

The Box-Cox plot for the Mean Thickness model suggests that a natural log transformation could be applied; however, the confidence interval for lambda includes one. Therefore, a transformation would

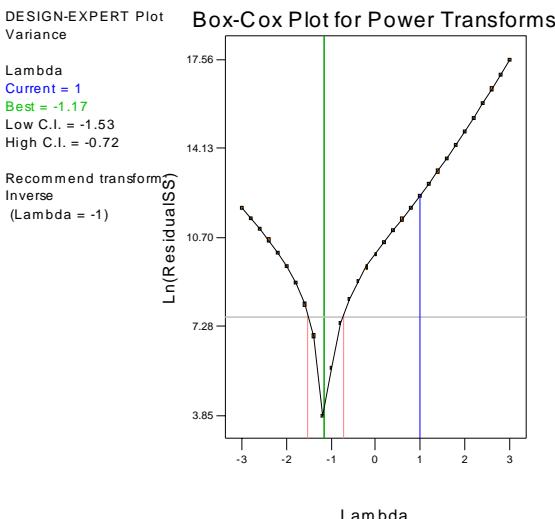

have a minimal effect. The natural log transformation applied to the Variance of Thickness model appears to be acceptable; however, again the confidence interval for lambda includes one.

15-8 In the 3^3 factorial design of Problem 12-12 one of the responses is a standard deviation. Use the Box-Cox method to investigate the usefulness of transformations for this response. Would your answer change if we used the variance of the response?

Because the confidence interval for lambda does not include one, a transformation should be applied. The natural log transformation should not be considered due to zero not being included in the confidence interval. The square root transformation appears to be acceptable. However, notice that the value of zero is very close to the lower confidence limit, and the minimizing value of lambda is between 0 and 0.5. It is likely that either the natural log or the square root transformation would work reasonably well.

15-9 Problem 12-10 suggests using the $\ln(s^2)$ as the response (refer to part b). Does the Box-Cox method indicate that a transformation is appropriate?

Because the confidence interval for lambda does not include one, a transformation should be applied. The confidence interval does not include zero; therefore, the natural log transformation is inappropriate. With the point estimate of lambda at -1.17 , the reciprocal transformation is appropriate.

15-10 Myers, Montgomery and Vining (2002) describe an experiment to study spermatozoa survival. The design factors are the amount of sodium citrate, the amount of glycerol, and equilibrium time, each at two levels. The response variable is the number of spermatozoa that survive out of fifty that were tested at each set of conditions. The data are in the following table. Analyze the data from this experiment with logistical regression.

Sodium Citrate	Glycerol	Equilibrium Time	Number Survived
-	-	-	34
+	-	-	20
-	+	-	8
+	+	-	21
-	-	+	30
+	-	+	20

This analysis shows that Glycerol (*B*) and the Sodium Citrate x Glycerol (*AB*) interaction have an effect on the survival rate of spermatozoa.

15-11 A soft drink distributor is studying the effectiveness of delivery methods. Three different types of hand trucks have been developed, and an experiment is performed in the company's methods engineering laboratory. The variable of interest is the delivery time in minutes (*y*); however, delivery time is also strongly related to the case volume delivered (*x*). Each hand truck is used four times and the data that follow are obtained. Analyze the data and draw the appropriate conclusions. Use $\alpha=0.05$.

		Hand	Truck	Type	
1	1	2	2	3	3
<i>y</i>	<i>x</i>	<i>y</i>	<i>x</i>	<i>y</i>	<i>x</i>
27	24	25	26	40	38
44	40	35	32	22	26
33	35	46	42	53	50
41	40	26	25	18	20

From the analysis performed in Minitab, hand truck does not have a statistically significant effect on delivery time. Volume, as expected, does have a significant effect.

15-12 Compute the adjusted treatment means and the standard errors of the adjusted treatment means for the data in Problem 15-11.

$$\text{adj } \bar{y}_{i\cdot} = \bar{y}_{i\cdot} - \hat{\beta}(\bar{x}_{i\cdot} - \bar{x}_{..})$$

$$\text{adj } \bar{y}_1 = \frac{145}{4} - (1.173) \left(\frac{139}{4} - \frac{398}{12} \right) = 34.39$$

$$\text{adj } \bar{y}_2 = \frac{132}{4} - (1.173) \left(\frac{125}{4} - \frac{398}{12} \right) = 35.25$$

$$\text{adj } \bar{y}_3 = \frac{133}{4} - (1.173) \left(\frac{134}{4} - \frac{398}{12} \right) = 32.86$$

$$S_{\text{adj.}\bar{y}_i} = \left[MS_E \left\{ \frac{1}{n} + \frac{(\bar{x}_i - \bar{x}_{..})^2}{E_{xx}} \right\} \right]^{\frac{1}{2}}$$

$$S_{\text{adj.}\bar{y}_1} = \left[5.24 \left\{ \frac{1}{4} + \frac{(34.75 - 33.17)^2}{884.50} \right\} \right]^{\frac{1}{2}} = 1.151$$

$$S_{\text{adj.}\bar{y}_2} = \left[5.24 \left\{ \frac{1}{4} + \frac{(31.25 - 33.17)^2}{884.50} \right\} \right]^{\frac{1}{2}} = 1.154$$

$$S_{\text{adj.}\bar{y}_3} = \left[5.24 \left\{ \frac{1}{4} + \frac{(33.50 - 33.17)^2}{884.50} \right\} \right]^{\frac{1}{2}} = 1.145$$

The solutions can also be obtained with Minitab as follows:

Minitab Output

Least Squares Means for Time			
Truck	Mean	SE Mean	
1	34.39	1.151

Treatments differ only at 10%.

15-14 Find the standard errors of the adjusted treatment means in Example 15-5.

From Example 14-4 $\bar{y}_1 = 40.38$, adj $\bar{y}_2 = 41.42$, adj $\bar{y}_3 = 37.78$

$$S_{adj.\bar{y}_1} = \left[2.54 \left\{ \frac{1}{5} + \frac{(25.20 - 24.13)^2}{195.60} \right\} \right]^{\frac{1}{2}} = 0.7231$$

$$S_{adj.\bar{y}_2} = \left[2.54 \left\{ \frac{1}{5} + \frac{(26.00 - 24.13)^2}{195.60} \right\} \right]^{\frac{1}{2}} = 0.7439$$

$$S_{adj.\bar{y}_3} = \left[2.54 \left\{ \frac{1}{5} + \frac{(21.20 - 24.13)^2}{195.60} \right\} \right]^{\frac{1}{2}} = 0.7871$$

15-15 Four different formulations of an industrial glue are being tested. The tensile strength of the glue when it is applied to join parts is also related to the application thickness. Five observations on strength (y) in pounds and thickness (x) in 0.01 inches are obtained for each formulation. The data are shown in the following table. Analyze these data and draw appropriate conclusions.

		Glue		Formulation			
1	1	2	2	3	3	4	4
y	x	y	x	y	x	y	x
46.5	13	48.7	12	46.3	15	44.7	16
45.9	14	49.0	10	47.1	14	43.0	15
49.8	12	50.1	11	48.9	11	51.0	10
46.1	12	48.5	12	48.2	11	48.1	12
44.3	14	45.2	14	50.3	10	48.6	11

From the analysis performed in Minitab, glue formulation does not have a statistically significant effect on strength. As expected, glue thickness does affect strength.

Glue	Mean	SE Mean
1	47.08	0.5355
2	47.64	0.5382
3	47.91	0.5301
4	47.43	0.5314

15-17 An engineer is studying the effect of cutting speed on the rate of metal removal in a machining operation. However, the rate of metal removal is also related to the hardness of the test specimen. Five observations are taken at each cutting speed. The amount of metal removed (y) and the hardness of the specimen (x) are shown in the following table. Analyze the data using analysis of covariance. Use $\alpha=0.05$.

		Cutting Speed (rpm)			
		1000	1200	1400	1400
		y	x	y	x
		68	120	112	165
		90	140	94	140
		98	150	65	120
		77	125	74	125
		88	136	85	133
				80	130

As shown in the analysis performed in Minitab, there is no difference in the rate of removal between the three cutting speeds. As expected, the hardness does have an impact on rate of removal.

Least Squares Means for Removal

Speed	Mean	SE Mean
1000	86.88	1.325
1200	86.44	1.318

1400	85.89	1.328
------	-------	-------

15-18 Show that in a single factor analysis of covariance with a single covariate a $100(1-\alpha)$ percent confidence interval on the i_{th} adjusted treatment mean is

$$\bar{y}_{i\cdot} - \hat{\beta}(\bar{x}_{i\cdot} - \bar{x}_{..}) \pm t_{\alpha/2,a(n-1)-1} \left[MS_E \left(\frac{1}{n} + \frac{(\bar{x}_{i\cdot} - \bar{x}_{..})^2}{E_{xx}} \right) \right]^{1/2}$$

Using this formula, calculate a 95 percent confidence interval on the adjusted mean of machine 1 in Example 14-4.

The $100(1-\alpha)$ percent interval on the i_{th} adjusted treatment mean would be

$$\bar{y}_{i\cdot} - \hat{\beta}(\bar{x}_{i\cdot} - \bar{x}_{..}) \pm t_{\alpha/2,a(n-1)-1} S_{adj\bar{y}_{i\cdot}}$$

since $\bar{y}_{i\cdot} - \hat{\beta}(\bar{x}_{i\cdot} - \bar{x}_{..})$ is an estimator of the i_{th} adjusted treatment mean. The standard error of the adjusted treatment mean is found as follows:

$$V(adj.\bar{y}_{i\cdot}) = V[\bar{y}_{i\cdot} - \hat{\beta}(\bar{x}_{i\cdot} - \bar{x}_{..})] = V(\bar{y}_{i\cdot}) + (\bar{x}_{i\cdot} - \bar{x}_{..})^2 V(\hat{\beta})$$

Since the $\{\bar{y}_{i\cdot}\}$ and $\hat{\beta}$ are independent. From regression analysis, we have $V(\hat{\beta}) = \frac{\sigma^2}{E_{xx}}$. Therefore,

$$V(adj.\bar{y}_{i\cdot}) = \frac{\sigma^2}{n} + \frac{(\bar{x}_{i\cdot} - \bar{x}_{..})^2 \sigma^2}{E_{xx}} = \sigma^2 \left[\frac{1}{n} + \frac{(\bar{x}_{i\cdot} - \bar{x}_{..})^2}{E_{xx}} \right]$$

Replacing σ^2 by its estimator MS_E , yields

$$\hat{V}(adj.\bar{y}_{i\cdot}) = MS_E \left[\frac{1}{n} + \frac{(\bar{x}_{i\cdot} - \bar{x}_{..})^2}{E_{xx}} \right] \text{ or}$$

$$S(adj.\bar{y}_{i\cdot}) = \sqrt{MS_E \left[\frac{1}{n} + \frac{(\bar{x}_{i\cdot} - \bar{x}_{..})^2}{E_{xx}} \right]}$$

Substitution of this result into $\bar{y}_{i\cdot} - \hat{\beta}(\bar{x}_{i\cdot} - \bar{x}_{..}) \pm t_{\alpha/2,a(n-1)-1} S_{adj\bar{y}_{i\cdot}}$ will produce the desired confidence interval. A 95% confidence interval on the mean of machine 1 would be found as follows:

$$\begin{aligned} adj.\bar{y}_{i\cdot} &= \bar{y}_{i\cdot} - \hat{\beta}(\bar{x}_{i\cdot} - \bar{x}_{..}) = 40.38 \\ S(adj.\bar{y}_{i\cdot}) &= 0.7231 \\ [40.38 \pm t_{0.025,11}(0.7231)] & \\ [40.38 \pm (2.20)(0.7231)] & \\ [40.38 \pm 1.59] & \end{aligned}$$

Therefore, $38.79 \leq \mu_1 \leq 41.96$, where μ_1 denotes the true adjusted mean of treatment one.

15-19 Show that in a single-factor analysis of covariance with a single covariate, the standard error of the difference between any two adjusted treatment means is

$$S_{Adj\bar{y}_i - Adj\bar{y}_{j.}} = \left[MS_E \left(\frac{2}{n} + \frac{(\bar{x}_{i.} - \bar{x}_{..})^2}{E_{xx}} \right) \right]^{\frac{1}{2}}$$

$$adj.\bar{y}_{i.} - adj.\bar{y}_{j.} = \bar{y}_{i.} - \hat{\beta}(\bar{x}_{i.} - \bar{x}_{..}) - [\bar{y}_{j.} - \hat{\beta}(\bar{x}_{j.} - \bar{x}_{..})]$$

$$adj.\bar{y}_{i.} - adj.\bar{y}_{j.} = \bar{y}_{i.} - \bar{y}_{j.} - \hat{\beta}(\bar{x}_{i.} - \bar{x}_{j.})$$

The variance of this statistic is

$$V[\bar{y}_{i.} - \bar{y}_{j.} - \hat{\beta}(\bar{x}_{i.} - \bar{x}_{j.})] = V(\bar{y}_{i.}) + V(\bar{y}_{j.}) + (\bar{x}_{i.} - \bar{x}_{j.})^2 V(\hat{\beta})$$

$$= \frac{\sigma^2}{n} + \frac{\sigma^2}{n} + \frac{(\bar{x}_{i.} - \bar{x}_{j.})^2 \sigma^2}{E_{xx}} = \sigma^2 \left[\frac{2}{n} + \frac{(\bar{x}_{i.} - \bar{x}_{j.})^2}{E_{xx}} \right]$$

Replacing σ^2 by its estimator MS_E , , and taking the square root yields the standard error

$$S_{Adj\bar{y}_i - Adj\bar{y}_{j.}} = \left[MS_E \left(\frac{2}{n} + \frac{(\bar{x}_{i.} - \bar{x}_{..})^2}{E_{xx}} \right) \right]^{\frac{1}{2}}$$

15-20 Discuss how the operating characteristic curves for the analysis of variance can be used in the analysis of covariance.

To use the operating characteristic curves, fixed effects case, we would use as the parameter Φ^2 ,

$$\Phi^2 = \frac{a \sum \tau_i^2}{n \sigma^2}$$

The test has $a-1$ degrees of freedom in the numerator and $a(n-1)-1$ degrees of freedom in the denominator.
